Article 100 Definitions

Voltage, Nominal....

Informational Note No. 3: Certain 48-volt DC battery units have a charging float voltage up to 58 volts. In DC applications 60 volts is used to cover the entire range of float voltages.

Article 110

110.27 Guarding of Live Part
(A) Live Parts Guarded Against Accidental Contact. Except as elsewhere required or permitted by this Code, live parts of electrical equipment operating at 50 volts AC/60 volts DC or more shall be guarded against accidental contact by approved enclosures or by any of the following means:

Article 200 Use and Identification of Grounded Conductors

200.7
(B) Circuits of Less Than 50 Volts AC. A conductor with white or gray color insulation or three continuous white stripes or having a marking of white or gray at the termination for circuits of less than 50 volts AC shall be required to be grounded only as required by 250.20(A).

C) Circuits of 50 Volts AC or More. The use of insulation that is white or gray or that has three continuous white or gray stripes for other than a grounded conductor for circuits of 50 volts AC or more shall be permitted only as in (1) and (2).

Article 215 Feeders

215.12(C)(2) Feeders Supplied from Direct-Current Systems. Where a feeder is supplied from a dc system operating at more than 50 volts, each ungrounded conductor of 4 AWG or larger shall be identified by polarity at all termination, connection, and splice points by marking tape, tagging, or other approved means; each ungrounded conductor of 6 AWG or smaller shall be identified by polarity at all termination, connection, and splice points in compliance with 215.12(C)(2)(a) and (b). The identification methods utilized for conductors originating within each feeder panelboard or similar feeder distribution equipment shall be documented in a manner that is readily available or shall be permanently posted at each feeder panelboard or similar feeder distribution equipment.

Article 430 Motors, Motor Circuits, and Controllers

430.232 Where Required. Exposed live parts of motors and controllers operating at 50 volts DC or more between terminals shall be guarded against accidental contact by enclosure or by location as follows:

430.233 Guards for Attendants. Where live parts of motors or controllers operating at over 50 volts AC to ground are guarded against accidental contact only by location as specified in 430.232, and where adjustment or other attendance may be necessary during the operation of the apparatus, suitable insulating mats or platforms shall be provided so that the attendant cannot readily touch live parts unless standing on the mats or platforms.

Article 445 Generators

445.14 Protection of Live Parts. Live parts of generators operated at more than 50 volts AC/60 volts DC to ground shall not be exposed to accidental contact where accessible to unqualified persons.

Article 460 Capacitors

460.6 (A) Time of Discharge. The residual voltage of a capacitor shall be reduced to 50 volts DC, nominal, or less within 1 minute after the capacitor is disconnected from the source of supply.

460.28(A) Means for Discharge. A means shall be provided to reduce the residual voltage of a capacitor to 50 volts DC or less within 5 minutes after the capacitor is disconnected from the source of supply.

Article 480 Storage Batteries

480.5 Overcurrent Protection for Prime Movers. Overcurrent protection shall not be required for conductors from a battery with a nominal voltage of 60 volts DC or less if the battery provides power for starting, ignition, or control of prime movers. Section 300.3 shall not apply to these conductors.

480.6 DC Disconnect Methods. (A) Disconnecting Means. A disconnecting means shall be provided for all ungrounded conductors derived from a stationary battery system with a nominal voltage over 60 volts DC. A disconnecting means shall be readily accessible and located within sight of the battery system.

Article 522 Control Systems for Permanent Amusement Attractions

522.25 Ungrounded Control Circuits. Separately derived ac and 2-wire dc circuits and systems 50 volts AC/60 volts DC or greater shall be permitted to be ungrounded, provided that all the following conditions are met:

Article 625

625.18 Interlock. Electric vehicle supply equipment shall be provided with an interlock that de-energizes the electric vehicle connector whenever the electrical connector is uncoupled from the electric vehicle. An interlock shall not be required for portable cord-and-plug-connected electric vehicle supply equipment intended for connection to
receptacle outlets rated at 125 volts, single phase, 15 and 20 amperes. An interlock shall not be required for dc supplies less than 60 volts dc.

625.19 Automatic De-Energization of Cable. The electric vehicle supply equipment or the cable-connector combination of the equipment shall be provided with an automatic means to de-energize the cable conductors and electric vehicle connector upon exposure to strain that could result in either cable rupture or separation of the cable from the electric connector and exposure of live parts. Automatic means to de-energize the cable conductors and electric vehicle connector shall not be required for portable cord-and-plug-connected electric vehicle supply equipment intended for connection to receptacle outlets rated at 125 volts, single phase, 15 and 20 amperes. An interlock shall not be required for dc supplies less than 60 volts dc.

625.44 Electric Vehicle Supply Equipment Connection. Electric vehicle supply equipment shall be permitted to be cord and plug-connected to the premises wiring system in accordance with one of the following:

(A) Connections to 125-Volt, Single-Phase, 15 and 20-Ampere Receptacle Outlets. Electric vehicle supply equipment intended for connection to non-locking, 2-pole, 3-wire grounding-type receptacle outlets rated at 125 V, single phase, 15 and 20 amperes or from a supply of less than 60 volts dc.

(B) Systems Exceeding 50 Volts Direct Current. Insulated conductors shall be permitted to be run without insulated support, provided they are protected from physical damage. Bare copper or aluminum conductors shall be permitted where supported on insulators.

(C) Systems Exceeding 50 Volts Direct Current. Insulated conductors shall be permitted to be run on insulated supports, provided they are protected from physical damage. Bare copper or aluminum conductors shall be permitted where supported on insulators and guarded against accidental contact up to the point of termination in accordance with 110.27.

Article 720 Circuits and Equipment Operating at Less than 50 Volts

720.1 Scope. This article covers installations operating at less than 50 volts, alternating current, or 60 volts direct current or alternating current.

720.11 Mechanical Execution of Work. Circuits operating at less than 50 volts AC or 60 volts DC shall be installed in a neat and workmanlike manner. Cables shall be supported by the building structure in such a manner that the cable will not be damaged by normal building use.

Statement of Problem and Substantiation for Public Comment

Over the past decade numerous code articles have been placed into the NEC as a result of the increased resurgence of DC systems. These systems, similar to their AC counterpart, have mandated code requirements that must be met when the system voltage exceeds a certain threshold. For years the system threshold for many of the requirements has been kept at the 50 volt level. While this is appropriate for AC systems, it can create confusion to the user of the document when applied to a 48 DC batteries during charging where a “float voltage” is common at 58 volts. The float voltage can vary significantly depending on battery chemistry, battery construction, and the actual ambient temperature. This voltage may be constant for the entire duration of the charge or can fluctuate. Some 48 volt DC systems stay above the 50 volt threshold for 99% of the time for applications such as telecommunications, UPS systems and emergency lighting.

This elevated voltage may create confusion since various AHJ’s might see 58 volts and mandate that a code rule must be followed since the 50 volt threshold has been increased. To resolve these issues a DC task group was formed to research the DC systems found in the NEC and to correlate the various DC topics that were being added to the NEC. The task group recommended the use of 60 volt DC throughout the code to eliminate the confusion that could arise from the elevated float voltage. The intent of the task group was to provide a consistent use of the voltage threshold within the NEC document.

For the 2017 NEC Revision Cycle, a task group was formed to correlate the use of the 50/60V threshold and provide public comments for the second draft. The task group members Larry Ayer (Chair), Bill Cantor, Donny Cook, Jim Dollard (Co-Chair), John Kovacik (DC Task Group Chair), Ernie Gallo, Vince Saporita, and Jim White provided input and guidance for these recommendations.

To correlate the use of 50 volts for AC systems and 60 volts for DC systems, the recommended NEC changes are based on the following:
1. Where a code section refers to AC systems only and indicates 50 volts the acronym “AC” was added to provide clarity.

2. Where a code section refers to a requirement used only in a DC system at a 50 volt threshold, the voltage is revised to 60 volts and the term “DC” is added.

3. Where a code section indicates a 50 volt threshold, and the section is a requirement for both AC and DC systems, the text is revised as “50 volts AC/60 volts DC”.

4. When a code section refers to DC systems, and the term “nominal” is used, it will be deleted since the voltage threshold is increased to 60 volts.

5. A fine print note is being recommended in Article 100 below the definition for “Nominal Voltage” to provide additional information on float voltage.

NEC changes are being recommended for the following code sections:

1. *Add informational note after “Voltage, Nominal”. Informational note to read as follows:*

"Informational Note No. 3: Certain 48-volt DC battery units use a charging float voltage up to 58 volts. In DC applications 60 volts is used to cover the entire range of float voltages."

2. For section 110.27, “50 volts” is being changed to “50 volts AC/60 volts DC”. This will clarify the voltage threshold for AC and DC systems.

3. Section 200.7 (B) and (C) applies to conductor marking for AC systems only. “AC” is added after 50 volts to clarify that this requirement is only for AC systems.

4. Section 210.5(C)(2) was revised in the First draft that changed “50 volts” to “60 volts” to correlate with the new microgrid article. Revise section 215.12(C) from “50 volts” to “60 volts” to correlate with section 210.5(C)(2).

5. In section 445.14, revise “50 volts” to 50 volts AC/60 volts DC” to clarify that this requirement pertains to both AC and DC systems.

6. In sections 480.5 and 480.6 “50 volts” was changed to “60 volts” since these pertain to DC batteries and DC systems.

7. In section 522.25, “50 volts” is being changed to “50 volts AC / 60 volts DC” to clarify that this section pertains to both AC and DC systems and distinguishes between the two voltage systems and thresholds.

8. Article 625, Electrical Vehicle Charging System. Revise the text from “50 volts” to “60 volts” since these are DC systems.

9. Section 669.6(A) and (B) are DC systems. Revise the text from “50 volts” to “60 volts”

10. Section 690.71 (B) is a DC system with a threshold of 50 volts. Revise the text from “50 volts” to “60 volts DC”.

11. Article 720 Circuits and Equipment Operating at Less Than 50 Volts covers both AC and DC systems. To correlate the Title has been changed to “50 Volts AC/60 Volts DC”. The Scope 720.1 and section 720.11 have been modified to clarify that this Article applies to both systems with the corresponding voltage.

Committee Statement

Committee Action: Rejected
Resolution: Panel 1: See SR 24 Panel 2: Accept. CMP-2 supports consistency in moving from 50V to 60V Panel 3: Reject. Less than 50 volts AC is normally not considered to be a shock hazard based on NFPA 70E. Less than 100 volts DC is not considered to be safe. Pulsating DC is not taken into account but is covered in Table 11(B) in Chapter 9 of the NEC. Panel 4: The hazards associated with 50V AC and 60V dc are in conflict with many safety standards that set limits of 60V DC and 30V ac for accessible circuits in dry locations. The existing code language with nominal 50V allows for
temporary voltage variations above and below 50V. Article 706 addresses energy storage and limits specific to that application would be best addressed there. Panel 5: Reject. The submitter’s substantiation is incorrect. There is no provision in Article 200 to limit these requirements to AC systems only. Each of these requirements applies to both AC and DC systems. Limiting this to AC systems only would result in no identification requirements for grounded DC conductors. Panel 11: Reject. The current wording of 430.232 and 430.233 includes both AC and DC, changing this would limit it to only DC or AC. Panel 12: See Second Revision No. 3319, [also pending revisions to Article 625 on this topic when the Panel reviews] Panel 13: See SRs 3614, 3615, and 3616

Committee Statement
Committee Action: Rejected but see related SR
Statement: Panel 12: Reject but See SR No. 3318
Panel 19: CMP 19 advises an accept of PC 120 to make the change to the reference.
I read with interest the article authored by Wade Elliot in the July issue of Woodalls Campground Management relative to the changes in the upcoming 2017 electric code.

In short, I am in favor of the changes. Good Job!

Relative to the percentage of sites needing 50 amp service, you folks were dead accurate to the effect of all of the “cheaters” campers use to attempt to adapt their new R.V.s to an old campground. The Great Falls, MT KOA Campground recently did (with Loren as the engineer) a 76 site expansion. These 76 new sites were all supplied with 50 amp as well as 30 and 20 amp service. The reason? The bulk of the New Big R.V.s have 50 amp, 240 volt, 4 wire male plugs, and they need an appropriate receptacle to plug into. Relative to increasing the load calculations from the previous 9,600 volt amps (watts) to the 12,000 watts per site, I concur. Especially if they are only going to use 40% of the sites as a 50 amp rated site.

The ground rods at every R.V. pedestal was nothing less than stupid. In fact, stupid is too kind of an adjective. Anyone with a modicum of intelligence knew that putting ground rods at every R.V. site was/is beyond ridiculous. We here at Prairie Kraft Specialties work with a lot of campground around the country and I saw several occasions where the customer was adding an R.V. Site, etc. and ended up having to drive double ground rods; never mind the fact that they had a very sufficient mechanical equipment ground wire. Besides being ridiculous, I saw many cases where it got even worse. Namely, an ignorant inspector or park owner decided to tie the neutral to these ground rods also. Now we had multiple neutrals tied to ground throughout the campground (producing ground currents) which of course was not the intent of the code.

In one particular case the “Electrical Inspector” classified each campsite as a “service entrance” and made them tie the neutrals to the ground rod at each site! Of course, the Electrical Inspector’s justifications was “it’s what the code says”. Fortunately, the Campground Owner, who was way smarter than the Electrical Inspector, only did this long enough to get his inspection approved. He then reconnected the neutrals and equipment grounds as they should be.

Again, I found everything mentioned in Wade’s article to be favorable. Keep up the good work folks. Should anyone have any questions don’t hesitate to contact me.

Sincerely yours,
Loren Smith
PE and Owner of the Great Falls, MT KOA

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4503-NFPA 70-2015
Statement: Telecommunications Industry Association (TIA) in its revision process corrected an error in their numbering scheme. Hence the two new parts are ANSI/TIA-568.0-D (generic) and ANSI/TIA-568.1-D (commercial buildings). Current editions of the documents are also provided. Additional TIA standards are added for completeness. The ANSI designation for TIA standards is retained as these standards utilize the ANSI standards development process and should be so designated.
This is a request for clarification on the panel resolution statement on Public Input 107-NFPA 70-2014.

Statement of Problem and Substantiation for Public Comment

The Resolution on my PI stated: The issue of foreign systems installed in electrical wiring enclosures is addressed in Section 300.8. Electrical equipment enclosures should be installed in accordance with their associated installation instructions. Restricting foreign equipment such as pneumatic piping and other types of systems from entering industrial equipment enclosures and process control equipment is not practical in all instances or conditions.

Section 300.8 states: Raceways Can’t Be Used For Multitasking- which goes on to state that Raceways are to be used only for electrical conductors and cables. Nonelectrical components such as pipes or tubes for Steam, Water, and Gas must not be installed in electrical raceways or cable trays.

Observation from years of experience: Raceways, Cable Trays, Combined Electrical Process Control Panels, and Industrial Equipment Enclosures all have the same common denominator, Remote Power Sources running through them. Where Motor Control Centers main power is fed via Cable Trays, the Motor Control Centers feeds 120v/60hz to pressure switches, transmitters, lightning/surge protection and step down transformers that are located in these process control panels and industrial equipment enclosures via internal terminal blocks. What is also common in all is the wires are installed in conduits. Now when a Pressurized Water Line is installed in a Process Control Panel or an Industrial Equipment Enclosure and it leaks or burst, the water can travel back to the sources such has a Power Panel, Motor Control Center, and even a Power Transformer.

Clarification Request: When the Committee stated restricting foreign equipment such Pneumatic Piping and other types of systems was not practical, was that supposed to have included Pressurized Water Lines? It appeared that Pressurized Water Lines wording was totally omitted from the Resolution.

Committee Statement

Committee Action: Rejected
Article 100  Definitions

Scope. This article contains only those definitions essential to the application of this Code. It is not intended to include commonly defined general terms or commonly defined technical terms from related codes and standards. In general, only those terms that are used in two or more articles are defined in Article 100. Other definitions are included in the article in which they are used but may be referenced in Article 100.

Part I of this article contains definitions intended to apply wherever the terms are used throughout this Code. Part II contains definitions applicable to installations and equipment operating at over 1000 volts, nominal.

Part I.  General

Accessible (as applied to equipment).
Admitting close approach; not guarded by locked doors, elevation, or other effective means.

Accessible (as applied to wiring methods).
Capable of being removed or exposed without damaging the building structure or finish or not permanently closed in by the structure or finish of the building.

Accessible, Readily (Readily Accessible).
Capable of being easily reached for operation, service, or inspection without requiring actions such as the use of tools, the need to climb over or under, the need to remove obstacles, or the use of portable ladders or similar equipment.

Adjustable Speed Drive.
Power conversion equipment that provides a means of adjusting the speed of an electric motor.

Informational Note: A variable frequency drive is one type of electronic adjustable speed drive that controls the rotational speed of an ac electric motor by controlling the frequency and voltage of the electrical power supplied to the motor.

Adjustable Speed Drive System.
A combination of an adjustable speed drive, its associated motor(s), and auxiliary equipment.

Ampacity.
The maximum current, in amperes, that a conductor can carry continuously under the conditions of use without exceeding its temperature rating.

Appliance.
Utilization equipment, generally other than industrial, that is normally built in standardized sizes or types and is installed or connected as a unit to perform one or more functions such as clothes washing, air-conditioning, food mixing, deep frying, and so forth.

Approved.
Acceptable to the authority having jurisdiction.

Arc-Fault Circuit Interrupter (AFCI).
A device intended to provide protection from the effects of arc faults by recognizing characteristics unique to arcing and by functioning to de-energize the circuit when an arc fault is detected.

Askarel.
A generic term for a group of nonflammable synthetic chlorinated hydrocarbons used as electrical insulating media.

Informational Note: Askarels of various compositional types are used. Under arcing conditions, the gases produced, while consisting predominantly of noncombustible hydrogen chloride, can include varying amounts of combustible gases, depending on the askarel type.

Associated Apparatus [as applied to Hazardous (Classified) Locations].
Apparatus in which the circuits are not necessarily intrinsically safe themselves but that affects the energy in the intrinsically safe circuits and is relied on to maintain intrinsic safety. Such apparatus is one of the following:

1) Electrical apparatus that has an alternative type of protection for use in the appropriate hazardous (classified) location.  
2) Electrical apparatus not so protected that shall not be used within a hazardous (classified) location.

Informational Note No. 1: Associated apparatus has identified intrinsically safe connections for intrinsically safe apparatus and also may have connections for nonintrinsically safe apparatus.

Informational Note No. 2: An example of associated apparatus is an intrinsic safety barrier, which is a network designed to limit the energy (voltage and current) available to the protected circuit in the hazardous (classified) location, under specified fault conditions.
Associated Nonincendive Field Wiring Apparatus [as applied to Hazardous (Classified) Locations].

Apparatus in which the circuits are not necessarily nonincendive themselves but that affect the energy in nonincendive field wiring circuits and are relied upon to maintain nonincendive energy levels. Such apparatus are one of the following:

1. Electrical apparatus that has an alternative type of protection for use in the appropriate hazardous (classified) location

2. Electrical apparatus not so protected that shall not be used in a hazardous (classified) location

Informational Note: Associated nonincendive field wiring apparatus has designated associated nonincendive field wiring apparatus connections for nonincendive field wiring apparatus and may also have connections for other electrical apparatus.

Attachment Plug (Plug Cap) (Plug).

A device that, by insertion in a receptacle, establishes a connection between the conductors of the attached flexible cord and the conductors connected permanently to the receptacle.

Authority Having Jurisdiction (AHJ).

An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

Informational Note: The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

Automatic.

Performing a function without the necessity of human intervention.

Bathroom.

An area including a basin with one or more of the following: a toilet, a urinal, a tub, a shower, a bidet, or similar plumbing fixtures.

Battery System.

Interconnected battery subsystems consisting of one or more storage batteries and battery chargers, and can include inverters, converters, and associated electrical equipment.

Bonded (Bonding).

Connected to establish electrical continuity and conductivity.

Bonding Conductor or Jumper.

A reliable conductor to ensure the required electrical conductivity between metal parts required to be electrically connected.

Bonding Jumper, Equipment.

The connection between two or more portions of the equipment grounding conductor.

Bonding Jumper, Main.

The connection between the grounded circuit conductor and the equipment grounding conductor at the service.

Bonding Jumper, System.

The connection between the grounded circuit conductor and the supply-side bonding jumper, or the equipment grounding conductor, or both, at a separately derived system.

Branch Circuit.

The circuit conductors between the final overcurrent device protecting the circuit and the outlet(s).

Branch Circuit, Appliance.

A branch circuit that supplies energy to one or more outlets to which appliances are to be connected and that has no permanently connected luminaires that are not a part of an appliance.

Branch Circuit, General-Purpose.

A branch circuit that supplies two or more receptacles or outlets for lighting and appliances.

Branch Circuit, Individual.

A branch circuit that supplies only one utilization equipment.

Branch Circuit, Multiwire.

A branch circuit that consists of two or more ungrounded conductors that have a voltage between them, and a grounded conductor that has equal voltage between it and each ungrounded conductor of the circuit and that is connected to the neutral or grounded conductor of the system.
Building.
A structure that stands alone or that is separated from adjoining structures by fire walls.

Cabinet.
An enclosure that is designed for either surface mounting or flush mounting and is provided with a frame, mat, or trim in which a swinging door or doors are or can be hung.

Cable Routing Assembly.
A single channel or connected multiple channels, as well as associated fittings, forming a structural system that is used to support and route communications wires and cables, optical fiber cables, data cables associated with information technology and communications equipment, Class 2, Class 3, and Type PLTC cables, and power-limited fire alarm cables in plenum, riser, and general-purpose applications.

Charge Controller.
Equipment that controls dc voltage or dc current, or both, and that is used to charge a battery or other energy storage device.

Circuit Breaker.
A device designed to open and close a circuit by nonautomatic means and to open the circuit automatically on a predetermined overcurrent without damage to itself when properly applied within its rating.

Informational Note: The automatic opening means can be integral, direct acting with the circuit breaker, or remote from the circuit breaker.

Adjustable (as applied to circuit breakers).
A qualifying term indicating that the circuit breaker can be set to trip at various values of current, time, or both, within a predetermined range.

Instantaneous Trip (as applied to circuit breakers).
A qualifying term indicating that no delay is purposely introduced in the tripping action of the circuit breaker.

Inverse Time (as applied to circuit breakers).
A qualifying term indicating that there is purposely introduced a delay in the tripping action of the circuit breaker, which delay decreases as the magnitude of the current increases.

Nonadjustable (as applied to circuit breakers).
A qualifying term indicating that the circuit breaker does not have any adjustment to alter the value of the current at which it will trip or the time required for its operation.

Setting (of circuit breakers).
The value of current, time, or both, at which an adjustable circuit breaker is set to trip.

Coaxial Cable.
A cylindrical assembly composed of a conductor centered inside a metallic tube or shield, separated by a dielectric material, and usually covered by an insulating jacket.

Clothes Closet.
A nonhabitable room or space intended primarily for storage of garments and apparel.

Combustible Dust [as applied to Hazardous (Classified) Locations].
Dust particles that are 500 microns or smaller (material passing a U.S. No. 35 Standard Sieve as defined in ASTM E 11-13, Standard Specification for Wire Cloth and Sieves for Testing Purposes), and present a fire or explosion hazard when dispersed and ignited in air.

Combustible Gas Detection System [as applied to Hazardous (Classified) Locations].
A protection technique utilizing stationary gas detectors in industrial establishments.

Communications Equipment.
The electronic equipment that performs the telecommunications operations for the transmission of audio, video, and data, and includes power equipment (e.g., dc converters, inverters, and batteries), technical support equipment (e.g., computers), and conductors dedicated solely to the operation of the equipment.

Informational Note: This definition clearly indicates that the dc power equipment as well as computers are considered to be part of the communications equipment. As the telecommunications network transitions to a more data centric network, communications equipment will also include routers and servers essential to the transmission of audio, video, and data.

Communications Raceway.
An enclosed channel of nonmetallic materials designed expressly for holding communications wires and cables, optical fiber cables, data cables associated with information technology and communications equipment, Class 2, Class 3 and Type PLTC cables, and power-limited fire alarm cables in plenums, risers, and general-purpose applications.
Composite Optical Fiber Cable.
A cable containing optical fibers and current-carrying electrical conductors.
Concealed.
Rendered inaccessible by the structure or finish of the building.

Informational Note: Wires in concealed raceways are considered concealed, even though they may become accessible by withdrawing them.

Conductive Optical Fiber Cable.
A factory assembly of one or more optical fibers having an overall covering and containing non–current-carrying conductive member(s) such as metallic strength member(s), metallic vapor barrier(s), metallic armor or metallic sheath.

Conductor, Bare.
A conductor having no covering or electrical insulation whatsoever.

Conductor, Covered.
A conductor encased within material of composition or thickness that is not recognized by this Code as electrical insulation.

Conductor, Insulated.
A conductor encased within material of composition and thickness that is recognized by this Code as electrical insulation.

Conduit Body.
A separate portion of a conduit or tubing system that provides access through a removable cover(s) to the interior of the system at a junction of two or more sections of the system or at a terminal point of the system.

Boxes such as FS and FD or larger cast or sheet metal boxes are not classified as conduit bodies.

Connector, Pressure (Solderless).
A device that establishes a connection between two or more conductors or between one or more conductors and a terminal by means of mechanical pressure and without the use of solder.

Continuous Load.
A load where the maximum current is expected to continue for 3 hours or more.

Control Circuit.
The circuit of a control apparatus or system that carries the electric signals directing the performance of the controller but does not carry the main power current.

Control Drawing [as applied to Hazardous (Classified) Locations].
A drawing or other document provided by the manufacturer of the intrinsically safe or associated apparatus, or of the nonincendive field wiring apparatus or associated nonincendive field wiring apparatus, that details the allowed interconnections between the intrinsically safe and associated apparatus or between the nonincendive field wiring apparatus or associated nonincendive field wiring apparatus.

Controller.
A device or group of devices that serves to govern, in some predetermined manner, the electric power delivered to the apparatus to which it is connected.

Cooking Unit, Counter-Mounted.
A cooking appliance designed for mounting in or on a counter and consisting of one or more heating elements, internal wiring, and built-in or mountable controls.

Coordination, Selective (Selective Coordination).
Localization of an overcurrent condition to restrict outages to the circuit or equipment affected, accomplished by the selection and installation of overcurrent protective devices and their ratings or settings for the full range of available overcurrents, from overload to the maximum available fault current, and for the full range of overcurrent protective device opening times associated with those overcurrents.

Copper-Clad Aluminum Conductors.
Conductors drawn from a copper-clad aluminum rod, with the copper metallurgically bonded to an aluminum core, where the copper forms a minimum of 10 percent of the cross-sectional area of a solid conductor or each strand of a stranded conductor.

Cord Connector [as applied to Hazardous (Classified) Locations].
A fitting intended to terminate a cord or cable to a box or similar device and reduce the strain at points of termination and may include an explosionproof, a dust-ignitionproof, or a flameproof seal.

Cutout Box.
An enclosure designed for surface mounting that has swinging doors or covers secured directly to and telescoping with the walls of the enclosure.

Dead Front.
Without live parts exposed to a person on the operating side of the equipment.
Demand Factor.
The ratio of the maximum demand of a system, or part of a system, to the total connected load of a system or the part of the system under consideration.

Device.
A unit of an electrical system, other than a conductor, that carries or controls electric energy as its principal function.

Disconnecting Means.
A device, or group of devices, or other means by which the conductors of a circuit can be disconnected from their source of supply.

Dust-Ignitionproof [as applied to Hazardous (Classified) Locations].
Equipment enclosed in a manner that excludes dusts and does not permit arcs, sparks, or heat otherwise generated or liberated inside of the enclosure to cause ignition of exterior accumulations or atmospheric suspensions of a specified dust on or in the vicinity of the enclosure.

Dusttight.
Enclosures constructed so that dust will not enter under specified test conditions.

Informational Note No. 1: Enclosure Types 3, 3S, 3SX, 4, 4X, 5, 6, 6P, 12, 12K, and 13, per ANSI/NEMA 250-2014, *Enclosures for Electrical Equipment*, are considered dusttight and suitable for use in unclassified locations and in Class II, Division 2; Class III; and Zone 22 hazardous (classified) locations.

Informational Note No. 2: For further information, see ANSI/ISA-12.12.01-2013, *Nonincendive Electrical Equipment for Use in Class I and II, Division 2, and Class III, Divisions 1 and 2 Hazardous (Classified) Locations*.

Duty, Continuous.
Operation at a substantially constant load for an indefinitely long time.

Duty, Intermittent.
Operation for alternate intervals of (1) load and no load; or (2) load and rest; or (3) load, no load, and rest.

Duty, Periodic.
Intermittent operation in which the load conditions are regularly recurrent.

Duty, Short-Time.
Operation at a substantially constant load for a short and definite, specified time.

Duty, Varying.
Operation at loads, and for intervals of time, both of which may be subject to wide variation.

Dwelling, One-Family.
A building that consists solely of one dwelling unit.

Dwelling, Two-Family.
A building that consists solely of two dwelling units.

Dwelling, Multifamily.
A building that contains three or more dwelling units.

Dwelling Unit.
A single unit, providing complete and independent living facilities for one or more persons, including permanent provisions for living, sleeping, cooking, and sanitation.

Effective Ground-Fault Current Path.
An intentionally constructed, low-impedance electrically conductive path designed and intended to carry current under ground-fault conditions from the point of a ground fault on a wiring system to the electrical supply source and that facilitates the operation of the overcurrent protective device or ground-fault detectors.

Electric Power Production and Distribution Network.
Power production, distribution, and utilization equipment and facilities, such as electric utility systems that deliver electric power to the connected loads, that are external to and not controlled by an interactive system.

Electric Sign.
A fixed, stationary, or portable self-contained, electrically operated and/or electrically illuminated utilization equipment with words or symbols designed to convey information or attract attention.

Electric-Discharge Lighting.
Systems of illumination utilizing fluorescent lamps, high-intensity discharge (HID) lamps, or neon tubing.
Electrical Circuit Protective System
A system consisting of components and materials intended for installation as protection for specific electrical wiring systems with respect to the disruption of electrical circuit integrity upon exterior fire exposure.

Electronically Actuated Fuse.
An overcurrent protective device that generally consists of a control module that provides current-sensing, electronically derived time–current characteristics, energy to initiate tripping, and an interrupting module that interrupts current when an overcurrent occurs. Such fuses may or may not operate in a current-limiting fashion, depending on the type of control selected.

Enclosed.
Surrounded by a case, housing, fence, or wall(s) that prevents persons from accidentally contacting energized parts.

Enclosure.
The case or housing of apparatus, or the fence or walls surrounding an installation to prevent personnel from accidentally contacting energized parts or to protect the equipment from physical damage.

Informational Note: See Table 110.28 for examples of enclosure types.

Energized.
Electrically connected to, or is, a source of voltage.

Equipment.
A general term, including fittings, devices, appliances, luminaires, apparatus, machinery, and the like used as a part of, or in connection with, an electrical installation.

Informational Note: In addition to the items listed in the definition, equipment also describes air conditioning units, power outlets (such as recreational vehicle site supply equipment or marine power outlets), transformers, and other enclosures that contain electrical products.

Exclusive Control (as applied to electrical installations).
The party that is responsible for the installation, servicing, maintaining, or repair of electrical conductors, equipment, raceways, signaling and communication conductors, fiber optic cables, and other similar installations.

Explosionproof Equipment.
Equipment enclosed in a case that is capable of withstanding an explosion of a specified gas or vapor that may occur within it and of preventing the ignition of a specified gas or vapor surrounding the enclosure by sparks, flashes, or explosion of the gas or vapor within, and that operates at such an external temperature that a surrounding flammable atmosphere will not be ignited thereby.

Informational Note: For further information, see ANSI/UL 1203-2009, Explosion-Proof and Dust-Ignition-Proof Electrical Equipment for Use in Hazardous (Classified) Locations.

Exposed (as applied to live parts).
Capable of being inadvertently touched or approached nearer than a safe distance by a person.

Informational Note: This term applies to parts that are not suitably guarded, isolated, or insulated.

Exposed (as applied to wiring methods).
On or attached to the surface or behind panels designed to allow access.

Externally Operable.
Capable of being operated without exposing the operator to contact with live parts.

Feeder.
All circuit conductors between the service equipment, the source of a separately derived system, or other power supply source and the final branch-circuit overcurrent device.

Festoon Lighting.
A string of outdoor lights that is suspended between two points.

Field Evaluation Body (FEB).
An organization or part of an organization that performs field evaluations of electrical or other equipment. [NFPA 790, 2012]

Field Labeled (as applied to evaluated products).
Equipment or materials to which has been attached a label, symbol, or other identifying mark of an FEB indicating the equipment or materials were evaluated and found to comply with requirements as described in an accompanying field evaluation report. [NFPA 790, 2012]

Fitting.
An accessory such as a locknut, bushing, or other part of a wiring system that is intended primarily to perform a mechanical rather than an electrical function.
Garage.
A building or portion of a building in which one or more self-propelled vehicles can be kept for use, sale, storage, rental, repair, exhibition, or demonstration purposes.

Informational Note: For commercial garages, repair and storage, see Article 511.

Ground.
The earth.

Ground Fault.
An unintentional, electrically conductive connection between an ungrounded conductor of an electrical circuit and the normally non–current-carrying conductors, metallic enclosures, metallic raceways, metallic equipment, or earth.

Grounded (Grounding).
Connected (connecting) to ground or to a conductive body that extends the ground connection.

Grounded, Solidly.
Connected to ground without inserting any resistor or impedance device.

Grounded Conductor.
A system or circuit conductor that is intentionally grounded.

Ground-Fault Circuit Interrupter (GFCI).
A device intended for the protection of personnel that functions to de-energize a circuit or portion thereof within an established period of time when a current to ground exceeds the values established for a Class A device.

Informational Note: Class A ground-fault circuit interrupters trip when the current to ground is 6 mA or higher and do not trip when the current to ground is less than 4 mA. For further information, see UL 943, Standard for Ground-Fault Circuit Interrupters.

Ground-Fault Circuit Interrupter, Special Purpose (SPGFCI).
A device intended for the protection of personnel that functions to de-energize a circuit or portion of a circuit within an established period of time when a current to ground exceeds the values established for Class C, D, and E devices.

Informational Note: Classes C, D, and E ground-fault circuit interrupters trip when the current to ground is 20 mA or higher and do not trip when the current to ground is less than 15 mA. For further information, see UL 943C, Outline of Investigation for Special Purpose Ground-Fault Circuit Interrupters.

Ground-Fault Current Path.
An electrically conductive path from the point of a ground fault on a wiring system through normally non–current-carrying conductors, equipment, or the earth to the electrical supply source.

Informational Note: Examples of ground-fault current paths are any combination of equipment grounding conductors, metallic raceways, metallic cable sheaths, electrical equipment, and any other electrically conductive material such as metal, water, and gas piping; steel framing members; stucco mesh; metal ducting; reinforcing steel; shields of communications cables; and the earth itself.

Ground-Fault Protection of Equipment.
A system intended to provide protection of equipment from damaging line-to-ground fault currents by operating to cause a disconnecting means to open all ungrounded conductors of the faulted circuit. This protection is provided at current levels less than those required to protect conductors from damage through the operation of a supply circuit overcurrent device.

Grounding Conductor, Equipment (EGC).
The conductive path(s) that provides a ground-fault current path and connects normally non–current-carrying metal parts of equipment together and to the system grounded conductor or to the grounding electrode conductor, or both.

Informational Note No. 1: It is recognized that the equipment grounding conductor also performs bonding.

Informational Note No. 2: See 250.118 for a list of acceptable equipment grounding conductors.

Grounding Electrode.
A conducting object through which a direct connection to earth is established.

Grounding Electrode Conductor.
A conductor used to connect the system grounded conductor or the equipment to a grounding electrode or to a point on the grounding electrode system.

Guarded.
Covered, shielded, fenced, enclosed, or otherwise protected by means of suitable covers, casings, barriers, rails, screens, mats, or platforms to remove the likelihood of approach or contact by persons or objects to a point of danger.

Guest Room.
An accommodation combining living, sleeping, sanitary, and storage facilities within a compartment.
**Guest Suite.**
An accommodation with two or more contiguous rooms comprising a compartment, with or without doors between such rooms, that provides living, sleeping, sanitary, and storage facilities.

**Handhole Enclosure.**
An enclosure for use in underground systems, provided with an open or closed bottom, and sized to allow personnel to reach into, but not enter, for the purpose of installing, operating, or maintaining equipment or wiring or both.

**Hermetic Refrigerant Motor-Compressor.**
A combination consisting of a compressor and motor, both of which are enclosed in the same housing, with no external shaft or shaft seals, with the motor operating in the refrigerant.

**Hermetically Sealed [as applied to Hazardous (Classified) Locations].**
Equipment sealed against the entrance of an external atmosphere where the seal is made by fusion, for example, soldering, brazing, welding, or the fusion of glass to metal.

Informational Note: For further information, see ANSI/ISA-12.12.01-2013, Nonincendive Electrical Equipment for Use in Class I and II, Division 2, and Class III, Divisions 1 and 2 Hazardous (Classified) Locations.

**Hoistway.**
Any shaftway, hatchway, well hole, or other vertical opening or space in which an elevator or dumbwaiter is designed to operate.

**Hybrid System.**
A system comprised of multiple power sources. These power sources could include photovoltaic, wind, micro-hydro generators, engine-driven generators, and others, but do not include electric power production and distribution network systems. Energy storage systems such as batteries, flywheels, or superconducting magnetic storage equipment do not constitute a power source for the purpose of this definition. The energy regenerated by an overhauling (descending) elevator does not constitute a power source for the purpose of this definition.

**Identified (as applied to equipment).**
Recognizable as suitable for the specific purpose, function, use, environment, application, and so forth, where described in a particular Code requirement.

Informational Note: Some examples of ways to determine suitability of equipment for a specific purpose, environment, or application include investigations by a qualified testing laboratory (listing and labeling), an inspection agency, or other organizations concerned with product evaluation.

**In Sight From (Within Sight From, Within Sight).**
Where this Code specifies that one equipment shall be “in sight from,” “within sight from,” or “within sight of,” and so forth, another equipment, the specified equipment is to be visible and not more than 15 m (50 ft) distant from the other.

**Industrial Control Panel.**
An assembly of two or more components consisting of one of the following: (1) power circuit components only, such as motor controllers, overload relays, fused disconnect switches, and circuit breakers; (2) control circuit components only, such as push buttons, pilot lights, selector switches, timers, switches, and control relays; (3) a combination of power and control circuit components. These components, with associated wiring and terminals, are mounted on, or contained within, an enclosure or mounted on a subpanel.

The industrial control panel does not include the controlled equipment.

**Information Technology Equipment (ITE).**
Equipment and systems rated 1000 volts or less, normally found in offices or other business establishments and similar environments classified as ordinary locations, that are used for creation and manipulation of data, voice, video, and similar signals that are not communications equipment as defined in Part I of Article 100 and do not process communications circuits as defined in 800.2.

Informational Note: For information on listing requirements for both information technology equipment and communications equipment, see UL 60950-1-2014, Information Technology Equipment — Safety — Part 1: General Requirements or UL 62368-1-2014, Audio/Video Information and Communication Technology Equipment Part 1: Safety Requirements.

**Innerduct.**
A nonmetallic raceway placed within a larger raceway.

**Interactive Inverter.**
An inverter intended for use in parallel with an electric utility to supply common loads that may deliver power to the utility.

**Interactive System.**
An electric power production system that is operating in parallel with and capable of delivering energy to an electric primary source supply system.

**Interrupting Rating.**
The highest current at rated voltage that a device is identified to interrupt under standard test conditions.

Informational Note: Equipment intended to interrupt current at other than fault levels may have its interrupting rating implied in other ratings, such as horsepower or locked rotor current.

**Intersystem Bonding Termination.**
A device that provides a means for connecting intersystem bonding conductors for communications systems to the grounding electrode system.

**Isolated (as applied to location).**
Not readily accessible to persons unless special means for access are used.

**Intrinsically Safe Apparatus.**
Apparatus in which all the circuits are intrinsically safe.

**Intrinsically Safe System [as applied to Hazardous (Classified) Locations].**
An assembly of interconnected intrinsically safe apparatus, associated apparatus, and interconnecting cables, in that those parts of the system that may be used in hazardous (classified) locations are intrinsically safe circuits.

Informational Note: An intrinsically safe system may include more than one intrinsically safe circuit.

**Kitchen.**
An area with a sink and permanent provisions for food preparation and cooking.

**Labeled.**
Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

**Lighting Outlet.**
An outlet intended for the direct connection of a lampholder or luminaire.

**Lighting Track (Track Lighting).**
A manufactured assembly designed to support and energize luminaires that are capable of being readily repositioned on the track. Its length can be altered by the addition or subtraction of sections of track.

**Listed.**
Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

Informational Note: The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. Use of the system employed by the listing organization allows the authority having jurisdiction to identify a listed product.

**Live Parts.**
Energized conductive components.

**Location, Damp.**
Locations protected from weather and not subject to saturation with water or other liquids but subject to moderate degrees of moisture.

Informational Note: Examples of such locations include partially protected locations under canopies, marquees, roofed open porches, and like locations, and interior locations subject to moderate degrees of moisture, such as some basements, some barns, and some cold-storage warehouses.

**Location, Dry.**
A location not normally subject to dampness or wetness. A location classified as dry may be temporarily subject to dampness or wetness, as in the case of a building under construction.

**Location, Wet.**
Installations underground or in concrete slabs or masonry in direct contact with the earth; in locations subject to saturation with water or other liquids, such as vehicle washing areas; and in unprotected locations exposed to weather.

**Luminaire.**
A complete lighting unit consisting of a light source such as a lamp or lamps, together with the parts designed to position the light source and connect it to the power supply. It may also include parts to protect the light source or the ballast or to distribute the light. A lampholder itself is not a luminaire.

**Mobile Equipment.**
Equipment with electrical components suitable to be moved only with mechanical aids or is provided with wheels for movement by person(s) or powered devices.
Motor Control Center.
An assembly of one or more enclosed sections having a common power bus and principally containing motor control units.

Multioutlet Assembly.
A type of surface, flush, or freestanding raceway designed to hold conductors and receptacles, assembled in the field or at the factory.

Neutral Conductor.
The conductor connected to the neutral point of a system that is intended to carry current under normal conditions.

Neutral Point.
The common point on a wye-connection in a polyphase system or midpoint on a single-phase, 3-wire system, or midpoint of a single-phase portion of a 3-phase delta system, or a midpoint of a 3-wire, direct-current system.

Informational Note: At the neutral point of the system, the vectorial sum of the nominal voltages from all other phases within the system that utilize the neutral, with respect to the neutral point, is zero potential.

Nonautomatic.
Requiring human intervention to perform a function.

Nonconductive Optical Fiber Cable.
A factory assembly of one or more optical fibers having an overall covering and containing no electrically conductive materials.

Nonincendive Circuit [as applied to Hazardous (Classified) Locations].
A circuit, other than field wiring, in which any arc or thermal effect produced under intended operating conditions of the equipment, is not capable, under specified test conditions, of igniting the flammable gas–air, vapor–air, or dust–air mixture.

Informational Note: Conditions are described in ANSI/ISA-12.12.01-2013, Nonincendive Electrical Equipment for Use in Class I and II, Division 2, and Class III, Divisions 1 and 2 Hazardous (Classified) Locations.

Nonincendive Component [as applied to Hazardous (Classified) Locations].
A component having contacts for making or breaking an incendive circuit and the contacting mechanism is constructed so that the component is incapable of igniting the specified flammable gas–air or vapor–air mixture. The housing of a nonincendive component is not intended to exclude the flammable atmosphere or contain an explosion.

Informational Note: For further information, see ANSI/ISA-12.12.01-2013, Nonincendive Electrical Equipment for Use in Class I and II, Division 2, and Class III, Divisions 1 and 2 Hazardous (Classified) Locations.

Nonincendive Equipment [as applied to Hazardous (Classified) Locations].
Equipment having electrical/electronic circuitry that is incapable, under normal operating conditions, of causing ignition of a specified flammable gas–air, vapor–air, or dust–air mixture due to arcing or thermal means.

Informational Note: For further information, see ANSI/ISA-12.12.01-2013, Nonincendive Electrical Equipment for Use in Class I and II, Division 2, and Class III, Divisions 1 and 2 Hazardous (Classified) Locations.

Nonincendive Field Wiring [as applied to Hazardous (Classified) Locations].
Wiring that enters or leaves an equipment enclosure and, under normal operating conditions of the equipment, is not capable, due to arcing or thermal effects, of igniting the flammable gas–air, vapor–air, or dust–air mixture. Normal operation includes opening, shorting, or grounding the field wiring.

Nonincendive Field Wiring Apparatus [as applied to Hazardous (Classified) Locations].
Apparatus intended to be connected to nonincendive field wiring.

Informational Note: For further information, see ANSI/ISA-12.12.01-2013, Nonincendive Electrical Equipment for Use in Class I and II, Division 2, and Class III, Divisions 1 and 2 Hazardous (Classified) Locations.

Nonlinear Load.
A load where the wave shape of the steady-state current does not follow the wave shape of the applied voltage.

Informational Note: Electronic equipment, electronic/electric-discharge lighting, adjustable-speed drive systems, and similar equipment may be nonlinear loads.

Oil Immersion [as applied to Hazardous (Classified) Locations].
Electrical equipment immersed in a protective liquid in such a way that an explosive atmosphere that may be above the liquid or outside the enclosure cannot be ignited.

Optical Fiber Cable.
A factory assembly or field assembly of one or more optical fibers having an overall covering.

Informational Note: A field-assembled optical fiber cable is an assembly of one or more optical fibers within a jacket. The jacket, without optical fibers, is installed in a manner similar to conduit or raceway. Once the jacket is installed, the optical fibers are inserted into the jacket, completing the cable assembly.

Outlet.
A point on the wiring system at which current is taken to supply utilization equipment.
Outline Lighting.
An arrangement of incandescent lamps, electric-discharge lighting, or other electrically powered light sources to outline or call attention to certain features such as the shape of a building or the decoration of a window.

Overcurrent.
Any current in excess of the rated current of equipment or the ampacity of a conductor. It may result from overload, short circuit, or ground fault.

Informational Note: A current in excess of rating may be accommodated by certain equipment and conductors for a given set of conditions. Therefore, the rules for overcurrent protection are specific for particular situations.

Overcurrent Protective Device, Branch-Circuit.
A device capable of providing protection for service, feeder, and branch circuits and equipment over the full range of overcurrents between its rated current and its interrupting rating. Such devices are provided with interrupting ratings appropriate for the intended use but no less than 5000 amperes.

Overcurrent Protective Device, Supplementary.
A device intended to provide limited overcurrent protection for specific applications and utilization equipment such as luminaires and appliances. This limited protection is in addition to the protection provided in the required branch circuit by the branch-circuit overcurrent protective device.

Overload.
Operation of equipment in excess of normal, full-load rating, or of a conductor in excess of rated ampacity that, when it persists for a sufficient length of time, would cause damage or dangerous overheating. A fault, such as a short circuit or ground fault, is not an overload.

Panelboard.
A single panel or group of panel units designed for assembly in the form of a single panel, including buses and automatic overcurrent devices, and equipped with or without switches for the control of light, heat, or power circuits; designed to be placed in a cabinet or cutout box placed in or against a wall, partition, or other support; and accessible only from the front.

Photovoltaic (PV) System.
The total components and subsystem that, in combination, convert solar energy into electric energy for connection to a utilization load.

Plenum.
A compartment or chamber to which one or more air ducts are connected and that forms part of the air distribution system.

Portable Equipment.
Equipment with electrical components suitable to be moved by a single person without mechanical aids.

Power Outlet.
An enclosed assembly that may include receptacles, circuit breakers, fuseholders, fused switches, buses, and watt-hour meter mounting means; intended to supply and control power to mobile homes, recreational vehicles, park trailers, or boats or to serve as a means for distributing power required to operate mobile or temporarily installed equipment.

Premises Wiring (System).
Interior and exterior wiring, including power, lighting, control, and signal circuit wiring together with all their associated hardware, fittings, and wiring devices, both permanently and temporarily installed. This includes (a) wiring from the service point or power source to the outlets or (b) wiring from and including the power source to the outlets where there is no service point.

Such wiring does not include wiring internal to appliances, luminaires, motors, controllers, motor control centers, and similar equipment.

Informational Note: Power sources include, but are not limited to, interconnected or stand-alone batteries, solar photovoltaic systems, other distributed generation systems, or generators.

Pressurized [as applied to Hazardous (Classified) Locations].
The process of supplying an enclosure with a protective gas with or without continuous flow, at sufficient pressure to prevent the entrance of combustible dust or ignitable fibers/flyings.

Process Seal [as applied to Hazardous (Classified) Locations].
A seal between electrical systems and flammable or combustible process fluids where a failure could allow the migration of process fluids into the premises' wiring system.

Purged and Pressurized [as applied to Hazardous (Classified) Locations].
The process of (1) purging, supplying an enclosure with a protective gas at a sufficient flow and positive pressure to reduce the concentration of any flammable gas or vapor initially present to an acceptable level; and (2) pressurization, supplying an enclosure with a protective gas with or without continuous flow at sufficient pressure to prevent the entrance of a flammable gas or vapor, a combustible dust, or an ignitable fiber.

Informational Note: For further information, see ANSI/NFPA 496-2013, Purged and Pressurized Enclosures for Electrical Equipment.
**Qualified Person.**

One who has skills and knowledge related to the construction and operation of the electrical equipment and installations and has received safety training to recognize and avoid the hazards involved.

Informational Note: Refer to NFPA 70E-2012, *Standard for Electrical Safety in the Workplace*, for electrical safety training requirements.

**Raceway.**

An enclosed channel designed expressly for holding wires, cables, or busbars, with additional functions as permitted in this Code.

Informational Note: A raceway is identified within specific article definitions.

**Rainproof.**

Constructed, protected, or treated so as to prevent rain from interfering with the successful operation of the apparatus under specified test conditions.

**Raintight.**

Constructed or protected so that exposure to a beating rain will not result in the entrance of water under specified test conditions.

**Receptacle.**

A contact device installed at the outlet for the connection of an attachment plug. A single receptacle is a single contact device with no other contact device on the same yoke. A multiple receptacle is two or more contact devices on the same yoke.

**Receptacle Outlet.**

An outlet where one or more receptacles are installed.

**Remote-Control Circuit.**

Any electrical circuit that controls any other circuit through a relay or an equivalent device.

**Retrofit Kit.**

A general term for a complete subassembly of parts and devices for field conversion of utilization equipment.

**Sealable Equipment.**

Equipment enclosed in a case or cabinet that is provided with a means of sealing or locking so that live parts cannot be made accessible without opening the enclosure.

Informational Note: The equipment may or may not be operable without opening the enclosure.

**Separately Derived System.**

An electrical source, other than a service, having no direct connection(s) to circuit conductors of any other electrical source other than those established by grounding and bonding connections.

**Service.**

The conductors and equipment for delivering electric energy from the serving utility to the wiring system of the premises served.

**Service Cable.**

Service conductors made up in the form of a cable.

**Service Conductors.**

The conductors from the service point to the service disconnecting means.

**Service Conductors, Overhead.**

The overhead conductors between the service point and the first point of connection to the service-entrance conductors at the building or other structure.

**Service Conductors, Underground.**

The underground conductors between the service point and the first point of connection to the service-entrance conductors in a terminal box, meter, or other enclosure, inside or outside the building wall.

Informational Note: Where there is no terminal box, meter, or other enclosure, the point of connection is considered to be the point of entrance of the service conductors into the building.

**Service Drop.**

The overhead conductors between the utility electric supply system and the service point.

**Service-Entrance Conductors, Overhead System.**

The service conductors between the terminals of the service equipment and a point usually outside the building, clear of building walls, where joined by tap or splice to the service drop or overhead service conductors.
Service-Entrance Conductors, Underground System.
The service conductors between the terminals of the service equipment and the point of connection to the service lateral or underground service conductors.

Informational Note: Where service equipment is located outside the building walls, there may be no service-entrance conductors or they may be entirely outside the building.

Service Equipment.
The necessary equipment, usually consisting of a circuit breaker(s) or switch(es) and fuse(s) and their accessories, connected to the load end of service conductors to a building or other structure, or an otherwise designated area, and intended to constitute the main control and cutoff of the supply.

Service Lateral.
The underground conductors between the utility electric supply system and the service point.

Service Point.
The point of connection between the facilities of the serving utility and the premises wiring.

Informational Note: The service point can be described as the point of demarcation between where the serving utility ends and the premises wiring begins. The serving utility generally specifies the location of the service point based on the conditions of service.

Short-Circuit Current Rating.
The prospective symmetrical fault current at a nominal voltage to which an apparatus or system is able to be connected without sustaining damage exceeding defined acceptance criteria.

Show Window.
Any window used or designed to be used for the display of goods or advertising material, whether it is fully or partly enclosed or entirely open at the rear and whether or not it has a platform raised higher than the street floor level.

Signaling Circuit.
Any electrical circuit that energizes signaling equipment.

Simple Apparatus [as applied to Hazardous (Classified) Locations].
An electrical component or combination of components of simple construction with well-defined electrical parameters that does not generate more than 1.5 volts, 100 mA, and 25 mW, or a passive component that does not dissipate more than 1.3 watts and is compatible with the intrinsic safety of the circuit in which it is used.

Informational Note: The following apparatus are examples of simple apparatus:

1. Passive components; for example, switches, junction boxes, resistance temperature devices, and simple semiconductor devices such as LEDs
2. Sources of stored energy consisting of single components in simple circuits with well-defined parameters; for example, capacitors or inductors, whose values are considered when determining the overall safety of the system
3. Sources of generated energy; for example, thermocouples and photocells, that do not generate more than 1.5 volts, 100 mA, and 25 mW

Special Permission.
The written consent of the authority having jurisdiction.

Structure.
That which is built or constructed, other than equipment.

Surge Arrester.
A protective device for limiting surge voltages by discharging or bypassing surge current; it also prevents continued flow of follow current while remaining capable of repeating these functions.

Surge-Protective Device (SPD).
A protective device for limiting transient voltages by diverting or limiting surge current; it also prevents continued flow of follow current while remaining capable of repeating these functions and is designated as follows:

Type 1: Permanently connected SPDs intended for installation between the secondary of the service transformer and the line side of the service disconnect overcurrent device.

Type 2: Permanently connected SPDs intended for installation on the load side of the service disconnect overcurrent device, including SPDs located at the branch panel.

Type 3: Point of utilization SPDs.

Type 4: Component SPDs, including discrete components, as well as assemblies.

Informational Note: For further information on Type 1, Type 2, Type 3, and Type 4 SPDs, see UL 1449, Standard for Surge Protective Devices.
Switch, Bypass Isolation.
A manually operated device used in conjunction with a transfer switch to provide a means of directly connecting load conductors to a power source and of disconnecting the transfer switch.

Switch, General-Use.
A switch intended for use in general distribution and branch circuits. It is rated in amperes, and it is capable of interrupting its rated current at its rated voltage.

Switch, General-Use Snap.
A form of general-use switch constructed so that it can be installed in device boxes or on box covers, or otherwise used in conjunction with wiring systems recognized by this Code.

Switch, Isolating.
A switch intended for isolating an electrical circuit from the source of power. It has no interrupting rating, and it is intended to be operated only after the circuit has been opened by some other means.

Switch, Motor-Circuit.
A switch rated in horsepower that is capable of interrupting the maximum operating overload current of a motor of the same horsepower rating as the switch at the rated voltage.

Switch, Transfer.
An automatic or nonautomatic device for transferring one or more load conductor connections from one power source to another.

Switchboard.
A large single panel, frame, or assembly of panels on which are mounted on the face, back, or both, switches, overcurrent and other protective devices, buses, and usually instruments. These assemblies are generally accessible from the rear as well as from the front and are not intended to be installed in cabinets.

Switchgear.
An assembly completely enclosed on all sides and top with sheet metal (except for ventilating openings and inspection windows) and containing primary power circuit switching, interrupting devices, or both, with buses and connections. The assembly may include control and auxiliary devices. Access to the interior of the enclosure is provided by doors, removable covers, or both.

Informational Note: All switchgear subject to NEC requirements is metal enclosed. Switchgear rated below 1000 V or less may be identified as "low-voltage power circuit breaker switchgear." Switchgear rated over 1000 V may be identified as "metal-enclosed switchgear" or "metal-clad switchgear." Switchgear is available in non–arc-resistant or arc-resistant constructions.

Thermal Protector (as applied to motors).
A protective device for assembly as an integral part of a motor or motor-compressor that, when properly applied, protects the motor against dangerous overheating due to overload and failure to start.

Informational Note: The thermal protector may consist of one or more sensing elements integral with the motor or motor-compressor and an external control device.

Thermally Protected (as applied to motors).
The words Thermally Protected appearing on the nameplate of a motor or motor-compressor indicate that the motor is provided with a thermal protector.

Unclassified Locations [as applied to Hazardous (Classified) Locations].
Locations determined to be neither Class I, Division 1; Class I, Division 2; Class I, Zone 0; Class I, Zone 1; Class I, Zone 2; Class II, Division 1; Class II, Division 2; Class III, Division 1; Class III, Division 2; Zone 20; Zone 21; Zone 22; nor any combination thereof.

Ungrounded.
Not connected to ground or to a conductive body that extends the ground connection.

Uninterruptible Power Supply.
A power supply used to provide alternating current power to a load for some period of time in the event of a power failure.

Informational Note: In addition, it may provide a more constant voltage and frequency supply to the load, reducing the effects of voltage and frequency variations.

Utilization Equipment.
Equipment that utilizes electric energy for electronic, electromechanical, chemical, heating, lighting, or similar purposes.

Ventilated.
Provided with a means to permit circulation of air sufficient to remove an excess of heat, fumes, or vapors.
Volatile Flammable Liquid.
A flammable liquid having a flash point below 38°C (100°F), or a flammable liquid whose temperature is above its flash point, or a Class II combustible liquid that has a vapor pressure not exceeding 276 kPa (40 psia) at 38°C (100°F) and whose temperature is above its flash point.

Voltage (of a circuit).
The greatest root-mean-square (rms) (effective) difference of potential between any two conductors of the circuit concerned.
Informational Note: Some systems, such as 3-phase 4-wire, single-phase 3-wire, and 3-wire direct current, may have various circuits of various voltages.

Voltage, Nominal.
A nominal value assigned to a circuit or system for the purpose of conveniently designating its voltage class (e.g., 120/240 volts, 480Y/277 volts, 600 volts).
Informational Note No. 1: The actual voltage at which a circuit operates can vary from the nominal within a range that permits satisfactory operation of equipment.
Informational Note No. 2: See ANSI C84.1-2011, Voltage Ratings for Electric Power Systems and Equipment (60 Hz).

Voltage to Ground.
For grounded circuits, the voltage between the given conductor and that point or conductor of the circuit that is grounded; for ungrounded circuits, the greatest voltage between the given conductor and any other conductor of the circuit.

Watertight.
Constructed so that moisture will not enter the enclosure under specified test conditions.

Weatherproof.
Constructed or protected so that exposure to the weather will not interfere with successful operation.
Informational Note: Rainproof, raintight, or watertight equipment can fulfill the requirements for weatherproof where varying weather conditions other than wetness, such as snow, ice, dust, or temperature extremes, are not a factor.

Part II. Over 1000 Volts, Nominal

Electronically Actuated Fuse.
An overcurrent protective device that generally consists of a control module that provides current sensing, electronically derived time–current characteristics, energy to initiate tripping, and an interrupting module that interrupts current when an overcurrent occurs. Electronically actuated fuses may or may not operate in a current-limiting fashion, depending on the type of control selected.

Fuse.
An overcurrent protective device with a circuit-opening fusible part that is heated and severed by the passage of overcurrent through it.
Informational Note: A fuse comprises all the parts that form a unit capable of performing the prescribed functions. It may or may not be the complete device necessary to connect it into an electrical circuit.

Controlled Vented Power Fuse.
A fuse with provision for controlling discharge circuit interruption such that no solid material may be exhausted into the surrounding atmosphere.
Informational Note: The fuse is designed so that discharged gases will not ignite or damage insulation in the path of the discharge or propagate a flashover to or between grounded members or conduction members in the path of the discharge where the distance between the vent and such insulation or conduction members conforms to manufacturer’s recommendations.

Expulsion Fuse Unit (Expulsion Fuse).
A vented fuse unit in which the expulsion effect of gases produced by the arc and lining of the fuseholder, either alone or aided by a spring, extinguishes the arc.

Nonvented Power Fuse.
A fuse without intentional provision for the escape of arc gases, liquids, or solid particles to the atmosphere during circuit interruption.

Power Fuse Unit.
A vented, nonvented, or controlled vented fuse unit in which the arc is extinguished by being drawn through solid material, granular material, or liquid, either alone or aided by a spring.

Vented Power Fuse.
A fuse with provision for the escape of arc gases, liquids, or solid particles to the surrounding atmosphere during circuit interruption.

Multiple Fuse.
An assembly of two or more single-pole fuses.
Substation.
An assemblage of equipment containing switches, interrupting devices, protection relays, buses, transformers, switchgear, motor control centers, etc... through which electric energy is passed for the purpose of switching or modifying characteristics. A substation is generally of such size or complexity that it incorporates one or more buses and a multiplicity of electrical equipment; is usually the receiving point for more than one supply circuit to transform power from one voltage to another or from one system to another.

Switching Device.
A device designed to close, open, or both, one or more electrical circuits.

Circuit Breaker.
A switching device capable of making, carrying, and interrupting currents under normal circuit conditions, and also of making, carrying for a specified time, and interrupting currents under specified abnormal circuit conditions, such as those of short circuit.

Cutout.
An assembly of a fuse support with either a fuseholder, fuse carrier, or disconnecting blade. The fuseholder or fuse carrier may include a conducting element (fuse link) or may act as the disconnecting blade by the inclusion of a nonfusible member.

Disconnecting Means.
A device, group of devices, or other means whereby the conductors of a circuit can be disconnected from their source of supply.

Disconnecting (or Isolating) Switch (Disconnector, Isolator).
A mechanical switching device used for isolating a circuit or equipment from a source of power.

Interrupter Switch.
A switch capable of making, carrying, and interrupting specified currents.

Oil Cutout (Oil-Filled Cutout).
A cutout in which all or part of the fuse support and its fuse link or disconnecting blade is mounted in oil with complete immersion of the contacts and the fusible portion of the conducting element (fuse link) so that arc interruption by severing of the fuse link or by opening of the contacts will occur under oil.

Oil Switch.
A switch having contacts that operate under oil (or askarel or other suitable liquid).

Regulator Bypass Switch.
A specific device or combination of devices designed to bypass a regulator.

Statement of Problem and Substantiation for Public Comment

The UL 1008M Outline for meter-mounted transfer switches was recently amended by UL to allow for the connection of permanently installed optional standby system generators. The Scope of this outline in Section 1.3 clearly states that these types of devices be under the exclusive control of the serving utility provider, and for that reason are not under the purview of the NEC. UL does not define the term exclusive control, as UL writes product standards, not installation code. By adding this definition to the NEC, the NFPA can be clarity to the meaning of "exclusive control" as applied to the installation of electrical conductors and equipment. Meter mounted transfer switches are UL listed as utility equipment to be under the utilities exclusive control and when these devices are installed by the utility provider. By adding this language, when a contractor attempts to install one of these devices, the device will not be under the utilities exclusive control and will be under the purview of the NEC.

UL 1008M TRANSFER SWITCH EQUIPMENT, METER MOUNTED

1 Scope

1.1 These requirements cover automatic and non-automatic (manual) transfer switch equipment, operating at 600 V ac less, and intended for installation in a utility meter base, in ordinary locations only.

1.2 These devices are intended for use in optional standby systems only, and are intended for cord connection of a portable generator to power a premise wiring system, where the neutral (grounded circuit conductor) of the generator is not bonded to ground or the generator frame. Bonding of the neutral (grounded circuit conductor) to ground will occur within the meter base. These devices are not intended for use in Emergency or Legally Required Standby Systems.

1.3 The installation of these devices is intended to be under the exclusive control of the serving utility, and these are not considered under the purview of the National Electrical Code, NFPA 70.

1.4 An automatic transfer switch as covered by these requirements is a device that automatically transfers a common load from a normal supply to an alternate supply in the event of failure of the normal supply, and automatically returns the load to the normal supply when the normal supply is restored. An automatic transfer switch may be provided with a logic control circuit that inhibits automatic operation of the device from either a normal to an alternate supply, or from an alternate to a normal supply when the switch reverts to automatic operation upon loss of power to the load.

1.5 A non-automatic transfer switch as covered by these requirements is a device, operated manually by a physical action, or
electrically by a remote control, for transferring a common load between a normal and alternate supply.

1.6 A transfer switch may incorporate overcurrent protection for the main power circuits.

1.7 These requirements only cover transfer switches which are completely enclosed when installed in a meter base in conjunction with the electrical utility meter.

1.8 Transfer switches are rated in amperes and are considered to be acceptable for total system transfer, which includes control of motors, electric-heating loads, and transformer loads.

Committee Statement

Committee Action: Rejected
Resolution: The proposed definition refers to an individual, group or organization rather than describes what exclusive control is. The definition of exclusive control is not necessary and the need for this definition has not been substantiated.
Article 100  Definitions

Scope. This article contains only those definitions essential to the application of this Code. It is not intended to include commonly defined general terms or commonly defined technical terms from related codes and standards. In general, only those terms that are used in two or more articles are defined in Article 100. Other definitions are included in the article in which they are used but may be referenced in Article 100.

Part I of this article contains definitions intended to apply wherever the terms are used throughout this Code. Part II contains definitions applicable to installations and equipment operating at over 1000 volts, nominal.

Part I. General

Accessible (as applied to equipment).
Admitting close approach; not guarded by locked doors, elevation, or other effective means.

Accessible (as applied to wiring methods).
Capable of being removed or exposed without damaging the building structure or finish or not permanently closed in by the structure or finish of the building.

Accessible, Readily (Readily Accessible).
Capable of being easily reached for operation, service, or inspection without requiring actions such as the use of tools, the need to climb over or under, the need to remove obstacles, or the use of portable ladders or similar equipment.

Adjustable Speed Drive.
Power conversion equipment that provides a means of adjusting the speed of an electric motor.

Adjustable Speed Drive System.
A combination of an adjustable speed drive, its associated motor(s), and auxiliary equipment.

Ampacity.
The maximum current, in amperes, that a conductor can carry continuously under the conditions of use without exceeding its temperature rating.

Appliance.
Utilization equipment, generally other than industrial, that is normally built in standardized sizes or types and is installed or connected as a unit to perform one or more functions such as clothes washing, air-conditioning, food mixing, deep frying, and so forth.

Approved.
Acceptable to the authority having jurisdiction.

Arc-Fault Circuit Interrupter (AFCI).
A device intended to provide protection from the effects of arc faults by recognizing characteristics unique to arcing and by functioning to de-energize the circuit when an arc fault is detected.

Askarel.
A generic term for a group of nonflammable synthetic chlorinated hydrocarbons used as electrical insulating media.

Associated Apparatus [as applied to Hazardous (Classified) Locations]. (Chapter 5)
Apparatus in which the circuits are not necessarily intrinsically safe themselves but that affects the energy in the intrinsically safe circuits and is relied on to maintain intrinsic safety. Such apparatus is one of the following:

(1) Electrical apparatus that has an alternative type of protection for use in the appropriate hazardous (classified) location

(2) Electrical apparatus not so protected that shall not be used within a hazardous (classified) location

Informational Note No. 1: Associated apparatus has identified intrinsically safe connections for intrinsically safe apparatus and also may have connections for nonintrinsically safe apparatus.

Informational Note No. 2: An example of associated apparatus is an intrinsic safety barrier, which is a network designed to limit the energy (voltage and current) available to the protected circuit in the hazardous (classified) location, under specified fault conditions.
Associated Nonincendive Field Wiring Apparatus [as applied to Hazardous (Classified) Locations].

Apparatus in which the circuits are not necessarily nonincendive themselves but that affect the energy in nonincendive field wiring circuits and are relied upon to maintain nonincendive energy levels. Such apparatus are one of the following:

1. Electrical apparatus that has an alternative type of protection for use in the appropriate hazardous (classified) location
2. Electrical apparatus not so protected that shall not be used in a hazardous (classified) location

Informational Note: Associated nonincendive field wiring apparatus has designated associated nonincendive field wiring apparatus connections for nonincendive field wiring apparatus and may also have connections for other electrical apparatus.

Attachment Plug (Plug Cap) (Plug).

A device that, by insertion in a receptacle, establishes a connection between the conductors of the attached flexible cord and the conductors connected permanently to the receptacle.

Authority Having Jurisdiction (AHJ).

An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

Informational Note: The phrase “authority having jurisdiction,” or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief, fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

Automatic.

Performing a function without the necessity of human intervention.

Bathroom.

An area including a basin with one or more of the following: a toilet, a urinal, a tub, a shower, a bidet, or similar plumbing fixtures.

Battery System.

Interconnected battery subsystems consisting of one or more storage batteries and battery chargers, and can include inverters, converters, and associated electrical equipment.

Bonded (Bonding).

Connected to establish electrical continuity and conductivity.

Bonding Conductor or Jumper.

A reliable conductor to ensure the required electrical conductivity between metal parts required to be electrically connected.

Bonding Jumper, Equipment.

The connection between two or more portions of the equipment grounding conductor.

Bonding Jumper, Main.

The connection between the grounded circuit conductor and the equipment grounding conductor at the service.

Bonding Jumper, System.

The connection between the grounded circuit conductor and the supply-side bonding jumper, or the equipment grounding conductor, or both, at a separately derived system.

Branch Circuit.

The circuit conductors between the final overcurrent device protecting the circuit and the outlet(s).

Branch Circuit, Appliance.

A branch circuit that supplies energy to one or more outlets to which appliances are to be connected and that has no permanently connected luminaires that are not a part of an appliance.

Branch Circuit, General-Purpose.

A branch circuit that supplies two or more receptacles or outlets for lighting and appliances.

Branch Circuit, Individual.

A branch circuit that supplies only one utilization equipment.

Branch Circuit, Multiwire.

A branch circuit that consists of two or more ungrounded conductors that have a voltage between them, and a grounded conductor that has equal voltage between it and each ungrounded conductor of the circuit and that is connected to the neutral or grounded conductor of the system.
Building.
A structure that stands alone or that is separated from adjoining structures by fire walls.

Cabinet.
An enclosure that is designed for either surface mounting or flush mounting and is provided with a frame, mat, or trim in which a swinging door or doors are or can be hung.

Cable Routing Assembly.
A single channel or connected multiple channels, as well as associated fittings, forming a structural system that is used to support and route communications wires and cables, optical fiber cables, data cables associated with information technology and communications equipment, Class 2, Class 3, and Type PLTC cables, and power-limited fire alarm cables in plenum, riser, and general-purpose applications.

Charge Controller.
Equipment that controls dc voltage or dc current, or both, and that is used to charge a battery or other energy storage device.

Circuit Breaker.
A device designed to open and close a circuit by nonautomatic means and to open the circuit automatically on a predetermined overcurrent without damage to itself when properly applied within its rating.

Adjustable (as applied to circuit breakers).
A qualifying term indicating that the circuit breaker can be set to trip at various values of current, time, or both, within a predetermined range.

Instantaneous Trip (as applied to circuit breakers).
A qualifying term indicating that no delay is purposely introduced in the tripping action of the circuit breaker.

Inverse Time (as applied to circuit breakers).
A qualifying term indicating that there is purposely introduced a delay in the tripping action of the circuit breaker, which delay decreases as the magnitude of the current increases.

Nonadjustable (as applied to circuit breakers).
A qualifying term indicating that the circuit breaker does not have any adjustment to alter the value of the current at which it will trip or the time required for its operation.

Setting (of circuit breakers).
The value of current, time, or both, at which an adjustable circuit breaker is set to trip.

Coaxial Cable.
A cylindrical assembly composed of a conductor centered inside a metallic tube or shield, separated by a dielectric material, and usually covered by an insulating jacket.

Clothes Closet.
A nonhabitable room or space intended primarily for storage of garments and apparel.

Combustible Dust [as applied to Hazardous (Classified) Locations].
Dust particles that are 500 microns or smaller (material passing a U.S. No. 35 Standard Sieve as defined in ASTM E 11-13, Standard Specification for Wire Cloth and Sieves for Testing Purposes), and present a fire or explosion hazard when dispersed and ignited in air.

Explosion protection systems — Part 1: Determination of explosion indices of combustible dusts in air, for procedures for determining the explosibility of dusts.

Combustible Gas Detection System [as applied to Hazardous (Classified) Locations].
A protection technique utilizing stationary gas detectors in industrial establishments.

Communications Equipment.
The electronic equipment that performs the telecommunications operations for the transmission of audio, video, and data, and includes power equipment (e.g., dc converters, inverters, and batteries), technical support equipment (e.g., computers), and conductors dedicated solely to the operation of the equipment.

Communications Raceway.
An enclosed channel of nonmetallic materials designed expressly for holding communications wires and cables, optical fiber cables, data cables associated with information technology and communications equipment, Class 2, Class 3 and Type PLTC cables, and power-limited fire alarm cables in plenums, risers, and general-purpose applications.
Composite Optical Fiber Cable.
A cable containing optical fibers and current-carrying electrical conductors.

Concealed.
Rendered inaccessible by the structure or finish of the building.

Informational Note: Wires in concealed raceways are considered concealed, even though they may become accessible by withdrawing them.

Conductive Optical Fiber Cable.
A factory assembly of one or more optical fibers having an overall covering and containing non–current-carrying conductive member(s) such as metallic strength member(s), metallic vapor barrier(s), metallic armor or metallic sheath.

Conductor, Bare.
A conductor having no covering or electrical insulation whatsoever.

Conductor, Covered.
A conductor encased within material of composition or thickness that is not recognized by this Code as electrical insulation.

Conductor, Insulated.
A conductor encased within material of composition and thickness that is recognized by this Code as electrical insulation.

Conduit Body.
A separate portion of a conduit or tubing system that provides access through a removable cover(s) to the interior of the system at a junction of two or more sections of the system or at a terminal point of the system.

Boxes such as FS and FD or larger cast or sheet metal boxes are not classified as conduit bodies.

Connector, Pressure (Solderless).
A device that establishes a connection between two or more conductors or between one or more conductors and a terminal by means of mechanical pressure and without the use of solder.

Continuous Load.
A load where the maximum current is expected to continue for 3 hours or more.

Control Circuit.
The circuit of a control apparatus or system that carries the electric signals directing the performance of the controller but does not carry the main power current.

Control Drawing [as applied to Hazardous (Classified) Locations].
A drawing or other document provided by the manufacturer of the intrinsically safe or associated apparatus, or of the nonincendive field wiring apparatus or associated nonincendive field wiring apparatus, that details the allowed interconnections between the intrinsically safe and associated apparatus or between the nonincendive field wiring apparatus or associated nonincendive field wiring apparatus.

Controller.
A device or group of devices that serves to govern, in some predetermined manner, the electric power delivered to the apparatus to which it is connected.

Cooking Unit, Counter-Mounted.
A cooking appliance designed for mounting in or on a counter and consisting of one or more heating elements, internal wiring, and built-in or mountable controls.

Coordination, Selective (Selective Coordination).
Localization of an overcurrent condition to restrict outages to the circuit or equipment affected, accomplished by the selection and installation of overcurrent protective devices and their ratings or settings for the full range of available overcurrents, from overload to the maximum available fault current, and for the full range of overcurrent protective device opening times associated with those overcurrents.

Copper-Clad Aluminum Conductors.
Conductors drawn from a copper-clad aluminum rod, with the copper metallurgically bonded to an aluminum core, where the copper forms a minimum of 10 percent of the cross-sectional area of a solid conductor or each strand of a stranded conductor.

Cord Connector [as applied to Hazardous (Classified) Locations].
A fitting intended to terminate a cord or cable to a box or similar device and reduce the strain at points of termination and may include an explosionproof, a dust-ignitionproof, or a flameproof seal.

Cutout Box.
An enclosure designed for surface mounting that has swinging doors or covers secured directly to and telescoping with the walls of the enclosure.

Dead Front.
Without live parts exposed to a person on the operating side of the equipment.
Demand Factor.
The ratio of the maximum demand of a system, or part of a system, to the total connected load of a system or the part of the system under consideration.

Device.
A unit of an electrical system, other than a conductor, that carries or controls electric energy as its principal function.

Disconnecting Means.
A device, or group of devices, or other means by which the conductors of a circuit can be disconnected from their source of supply.

Dust-Ignitionproof [as applied to Hazardous (Classified) Locations].
Equipment enclosed in a manner that excludes dusts and does not permit arcs, sparks, or heat otherwise generated or liberated inside of the enclosure to cause ignition of exterior accumulations or atmospheric suspensions of a specified dust on or in the vicinity of the enclosure.

Informational Note: For further information on dust-ignitionproof enclosures, see ANSI/UL 1202-2013, Enclosures for Electrical Equipment, and ANSI/UL 1203-2013, Explosionproof and Dust-Ignitionproof Electrical Equipment for Hazardous (Classified) Locations.

Dusttight.
Enclosures constructed so that dust will not enter under specified test conditions.

Informational Note No. 1: Enclosure Types 3, 3S, 3SX, 4, 4X, 5, 6, 6P, 12, 12K, and 13, per ANSI/NEMA 250-2014, Enclosures for Electrical Equipment, are considered dusttight and suitable for use in unclassified locations and in Class II, Division 2; Class III; and Zone 22 hazardous (classified) locations.

Informational Note No. 2: For further information, see ANSI/ISA-12.12.01-2013, Nonincendive Electrical Equipment for Use in Class I and II, Division 2, and Class III, Divisions 1 and 2 Hazardous (Classified) Locations.

Duty, Continuous.
Operation at a substantially constant load for an indefinitely long time.

Duty, Intermittent.
Operation for alternate intervals of (1) load and no load; or (2) load and rest; or (3) load, no load, and rest.

Duty, Periodic.
Intermittent operation in which the load conditions are regularly recurrent.

Duty, Short-Time.
Operation at a substantially constant load for a short and definite, specified time.

Duty, Varying.
Operation at loads, and for intervals of time, both of which may be subject to wide variation.

Dwelling, One-Family.
A building that consists solely of one dwelling unit.

Dwelling, Two-Family.
A building that consists solely of two dwelling units.

Dwelling, Multifamily.
A building that contains three or more dwelling units.

Dwelling Unit.
A single unit, providing complete and independent living facilities for one or more persons, including permanent provisions for living, sleeping, cooking, and sanitation.

Effective Ground-Fault Current Path.
An intentionally constructed, low-impedance electrically conductive path designed and intended to carry current under ground-fault conditions from the point of a ground fault on a wiring system to the electrical supply source and that facilitates the operation of the overcurrent protective device or ground-fault detectors.

Electric Power Production and Distribution Network.
Power production, distribution, and utilization equipment and facilities, such as electric utility systems that deliver electric power to the connected loads, that are external to and not controlled by an interactive system.

Electric Sign.
A fixed, stationary, or portable self-contained, electrically operated and/or electrically illuminated utilization equipment with words or symbols designed to convey information or attract attention.

Electric-Discharge Lighting.
Systems of illumination utilizing fluorescent lamps, high-intensity discharge (HID) lamps, or neon tubing.
Electrical Circuit Protective System

A system consisting of components and materials intended for installation as protection for specific electrical wiring systems with respect to the disruption of electrical circuit integrity upon exterior fire exposure.

Electronically Actuated Fuse.

An overcurrent protective device that generally consists of a control module that provides current-sensing, electronically derived time–current characteristics, energy to initiate tripping, and an interrupting module that interrupts current when an overcurrent occurs. Such fuses may or may not operate in a current-limiting fashion, depending on the type of control selected.

Enclosed.

Surrounded by a case, housing, fence, or wall(s) that prevents persons from accidentally contacting energized parts.

Enclosure.

The case or housing of apparatus, or the fence or walls surrounding an installation to prevent personnel from accidentally contacting energized parts or to protect the equipment from physical damage.

Informational Note: See Table 110.28 for examples of enclosure types.

Energized.

Electrically connected to, or is, a source of voltage.

Equipment.

A general term, including fittings, devices, appliances, luminaires, apparatus, machinery, and the like used as a part of, or in connection with, an electrical installation.

Informational Note: In addition to the items listed in the definition, equipment also describes air conditioning units, power outlets (such as recreational vehicle site supply equipment or marine power outlets), transformers, and other enclosures that contain electrical products.

Explosionproof Equipment.

Equipment enclosed in a case that is capable of withstanding an explosion of a specified gas or vapor that may occur within it and of preventing the ignition of a specified gas or vapor surrounding the enclosure by sparks, flashes, or explosion of the gas or vapor within, and that operates at such an external temperature that a surrounding flammable atmosphere will not be ignited thereby.

Informational Note: For further information, see ANSI/UL 1203-2009, Explosion-Proof and Dust-Ignition-Proof Electrical Equipment for Use in Hazardous (Classified) Locations.

Exposed (as applied to live parts).

Capable of being inadvertently touched or approached nearer than a safe distance by a person.

Informational Note: This term applies to parts that are not suitably guarded, isolated, or insulated.

Exposed (as applied to wiring methods).

On or attached to the surface or behind panels designed to allow access.

Externally Operable.

Capable of being operated without exposing the operator to contact with live parts.

Feeder.

All circuit conductors between the service equipment, the source of a separately derived system, or other power supply source and the final branch-circuit overcurrent device.

Festoon Lighting.

A string of outdoor lights that is suspended between two points.

Field Evaluation Body (FEB).

An organization or part of an organization that performs field evaluations of electrical or other equipment. [NFPA 790, 2012]

Field Labeled (as applied to evaluated products).

Equipment or materials to which has been attached a label, symbol, or other identifying mark of an FEB indicating the equipment or materials were evaluated and found to comply with requirements as described in an accompanying field evaluation report. [NFPA 790, 2012]

Fitting.

An accessory such as a locknut, bushing, or other part of a wiring system that is intended primarily to perform a mechanical rather than an electrical function.

Garage.

A building or portion of a building in which one or more self-propelled vehicles can be kept for use, sale, storage, rental, repair, exhibition, or demonstration purposes.

Informational Note: For commercial garages, repair and storage, see Article 511.
Ground.
The earth.

Ground Fault.
An unintentional, electrically conductive connection between an ungrounded conductor of an electrical circuit and the normally non–current-carrying conductors, metallic enclosures, metallic raceways, metallic equipment, or earth.

Grounded (Grounding).
Connected (connecting) to ground or to a conductive body that extends the ground connection.

Grounded, Solidly.
Connected to ground without inserting any resistor or impedance device.

Grounded Conductor.
A system or circuit conductor that is intentionally grounded.

Ground-Fault Circuit Interrupter (GFCI).
A device intended for the protection of personnel that functions to de-energize a circuit or portion thereof within an established period of time when a current to ground exceeds the values established for a Class A device.

Informational Note: Class A ground-fault circuit interrupters trip when the current to ground is 6 mA or higher and do not trip when the current to ground is less than 4 mA. For further information, see UL 943, Standard for Ground-Fault Circuit Interrupters.

Ground-Fault Circuit Interrupter, Special Purpose (SPGFCI).
A device intended for the protection of personnel that functions to de-energize a circuit or portion of a circuit within an established period of time when a current to ground exceeds the values established for Class C, D, and E devices.

Informational Note: Classes C, D, and E ground-fault circuit interrupters trip when the current to ground is 20 mA or higher and do not trip when the current to ground is less than 15 mA. For further information, see UL 943C, Outline of Investigation for Special Purpose Ground-Fault Circuit Interrupters.

Ground-Fault Current Path.
An electrically conductive path from the point of a ground fault on a wiring system through normally non–current-carrying conductors, equipment, or the earth to the electrical supply source.

Informational Note: Examples of ground-fault current paths are any combination of equipment grounding conductors, metallic raceways, metallic cable sheaths, electrical equipment, and any other electrically conductive material such as metal, water, and gas piping; steel framing members; stucco mesh; metal ducting; reinforcing steel; shields of communications cables; and the earth itself.

Ground-Fault Protection of Equipment.
A system intended to provide protection of equipment from damaging line-to-ground fault currents by operating to cause a disconnecting means to open all ungrounded conductors of the faulted circuit. This protection is provided at current levels less than those required to protect conductors from damage through the operation of a supply circuit overcurrent device.

Grounding Conductor, Equipment (EGC).
The conductive path(s) that provides a ground-fault current path and connects normally non–current-carrying metal parts of equipment together and to the system grounded conductor or to the grounding electrode conductor, or both.

Informational Note No. 1: It is recognized that the equipment grounding conductor also performs bonding.

Informational Note No. 2: See 250.118 for a list of acceptable equipment grounding conductors.

Grounding Electrode.
A conducting object through which a direct connection to earth is established.

Grounding Electrode Conductor.
A conductor used to connect the system grounded conductor or the equipment to a grounding electrode or to a point on the grounding electrode system.

Guarded.
Covered, shielded, fenced, enclosed, or otherwise protected by means of suitable covers, casings, barriers, rails, screens, mats, or platforms to remove the likelihood of approach or contact by persons or objects to a point of danger.

Guest Room.
An accommodation combining living, sleeping, sanitary, and storage facilities within a compartment.

Guest Suite.
An accommodation with two or more contiguous rooms comprising a compartment, with or without doors between such rooms, that provides living, sleeping, sanitary, and storage facilities.
Handhole Enclosure.
An enclosure for use in underground systems, provided with an open or closed bottom, and sized to allow personnel to reach into, but not enter, for the purpose of installing, operating, or maintaining equipment or wiring or both.

Hermetic Refrigerant Motor-Compressor.
A combination consisting of a compressor and motor, both of which are enclosed in the same housing, with no external shaft or shaft seals, with the motor operating in the refrigerant.

Hermetically Sealed [as applied to Hazardous (Classified) Locations].
Equipment sealed against the entrance of an external atmosphere where the seal is made by fusion, for example, soldering, brazing, welding, or the fusion of glass to metal.

Informational Note: For further information, see ANSI/ISA-12.12.01-2013, Nonincendive Electrical Equipment for Use in Class I and II, Division 2, and Class III, Divisions 1 and 2 Hazardous (Classified) Locations.

Hoistway.
Any shaftway, hatchway, well hole, or other vertical opening or space in which an elevator or dumbwaiter is designed to operate.

Hybrid System.
A system comprised of multiple power sources. These power sources could include photovoltaic, wind, micro-hydro generators, engine-driven generators, and others, but do not include electric power production and distribution network systems. Energy storage systems such as batteries, flywheels, or superconducting magnetic storage equipment do not constitute a power source for the purpose of this definition. The energy regenerated by an overhauling (descending) elevator does not constitute a power source for the purpose of this definition.

Identified (as applied to equipment).
Recognizable as suitable for the specific purpose, function, use, environment, application, and so forth, where described in a particular Code requirement.

Informational Note: Some examples of ways to determine suitability of equipment for a specific purpose, environment, or application include investigations by a qualified testing laboratory (listing and labeling), an inspection agency, or other organizations concerned with product evaluation.

In Sight From (Within Sight From, Within Sight).
Where this Code specifies that one equipment shall be "in sight from," "within sight from," or "within sight of," and so forth, another equipment, the specified equipment is to be visible and not more than 15 m (50 ft) distant from the other.

Industrial Control Panel.
An assembly of two or more components consisting of one of the following: (1) power circuit components only, such as motor controllers, overload relays, fused disconnect switches, and circuit breakers; (2) control circuit components only, such as push buttons, pilot lights, selector switches, timers, switches, and control relays; (3) a combination of power and control circuit components. These components, with associated wiring and terminals, are mounted on, or contained within, an enclosure or mounted on a subpanel.
The industrial control panel does not include the controlled equipment.

Information Technology Equipment (ITE).
Equipment and systems rated 1000 volts or less, normally found in offices or other business establishments and similar environments classified as ordinary locations, that are used for creation and manipulation of data, voice, video, and similar signals that are not communications equipment as defined in Part I of Article 100 and do not process communications circuits as defined in 800.2.

Informational Note: For information on listing requirements for both information technology equipment and communications equipment, see UL 60950-1-2014, Information Technology Equipment — Safety — Part 1: General Requirements or UL 62368-1-2014, Audio/Video Information and Communication Technology Equipment Part 1: Safety Requirements.

Innerduct.
A nonmetallic raceway placed within a larger raceway.

Interactive Inverter.
An inverter intended for use in parallel with an electric utility to supply common loads that may deliver power to the utility.

Interactive System.
An electric power production system that is operating in parallel with and capable of delivering energy to an electric primary source supply system.

Interrupting Rating.
The highest current at rated voltage that a device is identified to interrupt under standard test conditions.

Informational Note: Equipment intended to interrupt current at other than fault levels may have its interrupting rating implied in other ratings, such as horsepower or locked rotor current.
**Intersystem Bonding Termination.**
A device that provides a means for connecting intersystem bonding conductors for communications systems to the grounding electrode system.

**Isolated (as applied to location).**
Not readily accessible to persons unless special means for access are used.

**Intrinsically Safe Apparatus.**
Apparatus in which all the circuits are intrinsically safe.

**Intrinsically Safe System [as applied to Hazardous (Classified) Locations].**
An assembly of interconnected intrinsically safe apparatus, associated apparatus, and interconnecting cables, in that those parts of the system that may be used in hazardous (classified) locations are intrinsically safe circuits.

Informational Note: An intrinsically safe system may include more than one intrinsically safe circuit.

**Kitchen.**
An area with a sink and permanent provisions for food preparation and cooking.

**Labeled.**
Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

**Lighting Outlet.**
An outlet intended for the direct connection of a lampholder or luminaire.

**Lighting Track (Track Lighting).**
A manufactured assembly designed to support and energize luminaires that are capable of being readily repositioned on the track. Its length can be altered by the addition or subtraction of sections of track.

**Listed.**
Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

Informational Note: The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. Use of the system employed by the listing organization allows the authority having jurisdiction to identify a listed product.

**Live Parts.**
Energized conductive components.

**Location, Damp.**
Locations protected from weather and not subject to saturation with water or other liquids but subject to moderate degrees of moisture.

Informational Note: Examples of such locations include partially protected locations under canopies, marquees, roofed open porches, and like locations, and interior locations subject to moderate degrees of moisture, such as some basements, some barns, and some cold-storage warehouses.

**Location, Dry.**
A location not normally subject to dampness or wetness. A location classified as dry may be temporarily subject to dampness or wetness, as in the case of a building under construction.

**Location, Wet.**
Installations underground or in concrete slabs or masonry in direct contact with the earth; in locations subject to saturation with water or other liquids, such as vehicle washing areas; and in unprotected locations exposed to weather.

**Luminaire.**
A complete lighting unit consisting of a light source such as a lamp or lamps, together with the parts designed to position the light source and connect it to the power supply. It may also include parts to protect the light source or the ballast or to distribute the light. A lampholder itself is not a luminaire.

**Mobile Equipment.**
Equipment with electrical components suitable to be moved only with mechanical aids or is provided with wheels for movement by person(s) or powered devices.

**Motor Control Center.**
An assembly of one or more enclosed sections having a common power bus and principally containing motor control units.
Multioutlet Assembly.
A type of surface, flush, or freestanding raceway designed to hold conductors and receptacles, assembled in the field or at the factory.

Neutral Conductor.
The conductor connected to the neutral point of a system that is intended to carry current under normal conditions.

Neutral Point.
The common point on a wye-connection in a polyphase system or midpoint on a single-phase, 3-wire system, or midpoint of a single-phase portion of a 3-phase delta system, or a midpoint of a 3-wire, direct-current system.

Informational Note: At the neutral point of the system, the vectorial sum of the nominal voltages from all other phases within the system that utilize the neutral, with respect to the neutral point, is zero potential.

Nonautomatic.
Requiring human intervention to perform a function.

Nonconductive Optical Fiber Cable.
A factory assembly of one or more optical fibers having an overall covering and containing no electrically conductive materials.

Nonincendive Circuit [as applied to Hazardous (Classified) Locations].
A circuit, other than field wiring, in which any arc or thermal effect produced under intended operating conditions of the equipment, is not capable, under specified test conditions, of igniting the flammable gas–air, vapor–air, or dust–air mixture.

Informational Note: Conditions are described in ANSI/ISA-12.12.01-2013, Nonincendive Electrical Equipment for Use in Class I and II, Division 2, and Class III, Divisions 1 and 2 Hazardous (Classified) Locations.

Nonincendive Component [as applied to Hazardous (Classified) Locations].
A component having contacts for making or breaking an incendive circuit and the contacting mechanism is constructed so that the component is incapable of igniting the specified flammable gas–air or vapor–air mixture. The housing of a nonincendive component is not intended to exclude the flammable atmosphere or contain an explosion.

Informational Note: For further information, see ANSI/ISA-12.12.01-2013, Nonincendive Electrical Equipment for Use in Class I and II, Division 2, and Class III, Divisions 1 and 2 Hazardous (Classified) Locations.

Nonincendive Equipment [as applied to Hazardous (Classified) Locations].
Equipment having electrical/electronic circuitry that is incapable, under normal operating conditions, of causing ignition of a specified flammable gas–air, vapor–air, or dust–air mixture due to arcing or thermal means.

Informational Note: For further information, see ANSI/ISA-12.12.01-2013, Nonincendive Electrical Equipment for Use in Class I and II, Division 2, and Class III, Divisions 1 and 2 Hazardous (Classified) Locations.

Nonincendive Field Wiring [as applied to Hazardous (Classified) Locations].
Wiring that enters or leaves an equipment enclosure and, under normal operating conditions of the equipment, is not capable, due to arcing or thermal effects, of igniting the flammable gas–air, vapor–air, or dust–air mixture. Normal operation includes opening, shorting, or grounding the field wiring.

Nonincendive Field Wiring Apparatus [as applied to Hazardous (Classified) Locations].
Apparatus intended to be connected to nonincendive field wiring.

Informational Note: For further information, see ANSI/ISA-12.12.01-2013, Nonincendive Electrical Equipment for Use in Class I and II, Division 2, and Class III, Divisions 1 and 2 Hazardous (Classified) Locations.

Nonlinear Load.
A load where the wave shape of the steady-state current does not follow the wave shape of the applied voltage.

Informational Note: Electronic equipment, electronic/electric-discharge lighting, adjustable-speed drive systems, and similar equipment may be nonlinear loads.

Oil Immersion [as applied to Hazardous (Classified) Locations].
Electrical equipment immersed in a protective liquid in such a way that an explosive atmosphere that may be above the liquid or outside the enclosure cannot be ignited.

Optical Fiber Cable.
A factory assembly or field assembly of one or more optical fibers having an overall covering.

Informational Note: A field-assembled optical fiber cable is an assembly of one or more optical fibers within a jacket. The jacket, without optical fibers, is installed in a manner similar to conduit or raceway. Once the jacket is installed, the optical fibers are inserted into the jacket, completing the cable assembly.

Outlet.
A point on the wiring system at which current is taken to supply utilization equipment.
Outline Lighting.
An arrangement of incandescent lamps, electric-discharge lighting, or other electrically powered light sources to outline or call attention to certain features such as the shape of a building or the decoration of a window.

Overcurrent.
Any current in excess of the rated current of equipment or the ampacity of a conductor. It may result from overload, short circuit, or ground fault.

Informational Note: A current in excess of rating may be accommodated by certain equipment and conductors for a given set of conditions. Therefore, the rules for overcurrent protection are specific for particular situations.

Overcurrent Protective Device, Branch-Circuit.
A device capable of providing protection for service, feeder, and branch circuits and equipment over the full range of overcurrents between its rated current and its interrupting rating. Such devices are provided with interrupting ratings appropriate for the intended use but no less than 5000 amperes.

Overcurrent Protective Device, Supplementary.
A device intended to provide limited overcurrent protection for specific applications and utilization equipment such as luminaires and appliances. This limited protection is in addition to the protection provided in the required branch circuit by the branch-circuit overcurrent protective device.

Overload.
Operation of equipment in excess of normal, full-load rating, or of a conductor in excess of rated ampacity that, when it persists for a sufficient length of time, would cause damage or dangerous overheating. A fault, such as a short circuit or ground fault, is not an overload.

Panelboard.
A single panel or group of panel units designed for assembly in the form of a single panel, including buses and automatic overcurrent devices, and equipped with or without switches for the control of light, heat, or power circuits; designed to be placed in a cabinet or cutout box placed in or against a wall, partition, or other support; and accessible only from the front.

Photovoltaic (PV) System.
The total components and subsystem that, in combination, convert solar energy into electric energy for connection to a utilization load.

Plenum.
A compartment or chamber to which one or more air ducts are connected and that forms part of the air distribution system.

Portable Equipment.
Equipment with electrical components suitable to be moved by a single person without mechanical aids.

Power Outlet.
An enclosed assembly that may include receptacles, circuit breakers, fuseholders, fused switches, buses, and watt-hour meter mounting means; intended to supply and control power to mobile homes, recreational vehicles, park trailers, or boats or to serve as a means for distributing power required to operate mobile or temporarily installed equipment.

Premises Wiring (System).
Interior and exterior wiring, including power, lighting, control, and signal circuit wiring together with all their associated hardware, fittings, and wiring devices, both permanently and temporarily installed. This includes (a) wiring from the service point or power source to the outlets or (b) wiring from and including the power source to the outlets where there is no service point.

Such wiring does not include wiring internal to appliances, luminaires, motors, controllers, motor control centers, and similar equipment.

Informational Note: Power sources include, but are not limited to, interconnected or stand-alone batteries, solar photovoltaic systems, other distributed generation systems, or generators.

Pressurized [as applied to Hazardous (Classified) Locations].
The process of supplying an enclosure with a protective gas with or without continuous flow, at sufficient pressure to prevent the entrance of combustible dust or ignitable fibers/flyings.

Process Seal [as applied to Hazardous (Classified) Locations].
A seal between electrical systems and flammable or combustible process fluids where a failure could allow the migration of process fluids into the premises’ wiring system.

Purged and Pressurized [as applied to Hazardous (Classified) Locations].
The process of (1) purging, supplying an enclosure with a protective gas at a sufficient flow and positive pressure to reduce the concentration of any flammable gas or vapor initially present to an acceptable level; and (2) pressurization, supplying an enclosure with a protective gas with or without continuous flow at sufficient pressure to prevent the entrance of a flammable gas or vapor, a combustible dust, or an ignitable fiber.

Informational Note: For further information, see ANSI/NFPA 496-2013, Purged and Pressurized Enclosures for Electrical Equipment.
Qualified Person.
One who has skills and knowledge related to the construction and operation of the electrical equipment and installations and has received safety training to recognize and avoid the hazards involved.

Informational Note: Refer to NFPA 70E-2012, Standard for Electrical Safety in the Workplace, for electrical safety training requirements.

Raceway.
An enclosed channel designed expressly for holding wires, cables, or busbars, with additional functions as permitted in this Code.

Informational Note: A raceway is identified within specific article definitions.

Rainproof.
Constructed, protected, or treated so as to prevent rain from interfering with the successful operation of the apparatus under specified test conditions.

Raintight.
Constructed or protected so that exposure to a beating rain will not result in the entrance of water under specified test conditions.

Receptacle.
A contact device installed at the outlet for the connection of an attachment plug. A single receptacle is a single contact device with no other contact device on the same yoke. A multiple receptacle is two or more contact devices on the same yoke.

Receptacle Outlet.
An outlet where one or more receptacles are installed.

Remote-Control Circuit.
Any electrical circuit that controls any other circuit through a relay or an equivalent device.

Retrofit Kit.
A general term for a complete subassembly of parts and devices for field conversion of utilization equipment.

Sealable Equipment.
Equipment enclosed in a case or cabinet that is provided with a means of sealing or locking so that live parts cannot be made accessible without opening the enclosure.

Informational Note: The equipment may or may not be operable without opening the enclosure.

Separately Derived System.
An electrical source, other than a service, having no direct connection(s) to circuit conductors of any other electrical source other than those established by grounding and bonding connections.

Service.
The conductors and equipment for delivering electric energy from the serving utility to the wiring system of the premises served.

Service Cable.
Service conductors made up in the form of a cable.

Service Conductors.
The conductors from the service point to the service disconnecting means.

Service Conductors, Overhead.
The overhead conductors between the service point and the first point of connection to the service-entrance conductors at the building or other structure.

Service Conductors, Underground.
The underground conductors between the service point and the first point of connection to the service-entrance conductors in a terminal box, meter, or other enclosure, inside or outside the building wall.

Informational Note: Where there is no terminal box, meter, or other enclosure, the point of connection is considered to be the point of entrance of the service conductors into the building.

Service Drop.
The overhead conductors between the utility electric supply system and the service point.

Service-Entrance Conductors, Overhead System.
The service conductors between the terminals of the service equipment and a point usually outside the building, clear of building walls, where joined by tap or splice to the service drop or overhead service conductors.
Service-Entrance Conductors, Underground System.
The service conductors between the terminals of the service equipment and the point of connection to the service lateral or underground service conductors.

Informational Note: Where service equipment is located outside the building walls, there may be no service-entrance conductors or they may be entirely outside the building.

Service Equipment.
The necessary equipment, usually consisting of a circuit breaker(s) or switch(es) and fuse(s) and their accessories, connected to the load end of service conductors to a building or other structure, or an otherwise designated area, and intended to constitute the main control and cutoff of the supply.

Service Lateral.
The underground conductors between the utility electric supply system and the service point.

Service Point.
The point of connection between the facilities of the serving utility and the premises wiring.

Informational Note: The service point can be described as the point of demarcation between where the serving utility ends and the premises wiring begins. The serving utility generally specifies the location of the service point based on the conditions of service.

Short-Circuit Current Rating.
The prospective symmetrical fault current at a nominal voltage to which an apparatus or system is able to be connected without sustaining damage exceeding defined acceptance criteria.

Show Window.
Any window used or designed to be used for the display of goods or advertising material, whether it is fully or partly enclosed or entirely open at the rear and whether or not it has a platform raised higher than the street floor level.

Signaling Circuit.
Any electrical circuit that energizes signaling equipment.

Simple Apparatus [as applied to Hazardous (Classified) Locations].
An electrical component or combination of components of simple construction with well-defined electrical parameters that does not generate more than 1.5 volts, 100 mA, and 25 mW, or a passive component that does not dissipate more than 1.3 watts and is compatible with the intrinsic safety of the circuit in which it is used.

Informational Note: The following apparatus are examples of simple apparatus:

1. Passive components; for example, switches, junction boxes, resistance temperature devices, and simple semiconductor devices such as LEDs
2. Sources of stored energy consisting of single components in simple circuits with well-defined parameters; for example, capacitors or inductors, whose values are considered when determining the overall safety of the system
3. Sources of generated energy; for example, thermocouples and photocells, that do not generate more than 1.5 volts, 100 mA, and 25 mW

Special Permission.
The written consent of the authority having jurisdiction.

Structure.
That which is built or constructed, other than equipment.

Surge Arrester.
A protective device for limiting surge voltages by discharging or bypassing surge current; it also prevents continued flow of follow current while remaining capable of repeating these functions.

Surge-Protective Device (SPD).
A protective device for limiting transient voltages by diverting or limiting surge current; it also prevents continued flow of follow current while remaining capable of repeating these functions and is designated as follows:

Type 1: Permanently connected SPDs intended for installation between the secondary of the service transformer and the line side of the service disconnect overcurrent device.

Type 2: Permanently connected SPDs intended for installation on the load side of the service disconnect overcurrent device, including SPDs located at the branch panel.

Type 3: Point of utilization SPDs.

Type 4: Component SPDs, including discrete components, as well as assemblies.

Informational Note: For further information on Type 1, Type 2, Type 3, and Type 4 SPDs, see UL 1449, Standard for Surge Protective Devices.
Switch, Bypass Isolation.
A manually operated device used in conjunction with a transfer switch to provide a means of directly connecting load conductors to a power source and of disconnecting the transfer switch.

Switch, General-Use.
A switch intended for use in general distribution and branch circuits. It is rated in amperes, and it is capable of interrupting its rated current at its rated voltage.

Switch, General-Use Snap.
A form of general-use switch constructed so that it can be installed in device boxes or on box covers, or otherwise used in conjunction with wiring systems recognized by this Code.

Switch, Isolating.
A switch intended for isolating an electrical circuit from the source of power. It has no interrupting rating, and it is intended to be operated only after the circuit has been opened by some other means.

Switch, Motor-Circuit.
A switch rated in horsepower that is capable of interrupting the maximum operating overload current of a motor of the same horsepower rating as the switch at the rated voltage.

Switch, Transfer.
An automatic or nonautomatic device for transferring one or more load conductor connections from one power source to another.

Switchboard.
A large single panel, frame, or assembly of panels on which are mounted on the face, back, or both, switches, overcurrent and other protective devices, buses, and usually instruments. These assemblies are generally accessible from the rear as well as from the front and are not intended to be installed in cabinets.

Switchgear.
An assembly completely enclosed on all sides and top with sheet metal (except for ventilating openings and inspection windows) and containing primary power circuit switching, interrupting devices, or both, with buses and connections. The assembly may include control and auxiliary devices. Access to the interior of the enclosure is provided by doors, removable covers, or both.

Informational Note: All switchgear subject to NEC requirements is metal enclosed. Switchgear rated below 1000 V or less may be identified as “low-voltage power circuit breaker switchgear.” Switchgear rated over 1000 V may be identified as “metal-enclosed switchgear” or “metal-clad switchgear.” Switchgear is available in non–arc-resistant or arc-resistant constructions.

Thermal Protector (as applied to motors).
A protective device for assembly as an integral part of a motor or motor-compressor that, when properly applied, protects the motor against dangerous overheating due to overload and failure to start.

Informational Note: The thermal protector may consist of one or more sensing elements integral with the motor or motor-compressor and an external control device.

Thermally Protected (as applied to motors).
The words Thermally Protected appearing on the nameplate of a motor or motor-compressor indicate that the motor is provided with a thermal protector.

Unclassified Locations [as applied to Hazardous (Classified) Locations].
Locations determined to be neither Class I, Division 1; Class I, Division 2; Class I, Zone 0; Class I, Zone 1; Class I, Zone 2; Class II, Division 1; Class II, Division 2; Class III, Division 1; Class III, Division 2; Zone 20; Zone 21; Zone 22; nor any combination thereof.

Ungrounded.
Not connected to ground or to a conductive body that extends the ground connection.

Uninterruptible Power Supply.
A power supply used to provide alternating current power to a load for some period of time in the event of a power failure.

Informational Note: In addition, it may provide a more constant voltage and frequency supply to the load, reducing the effects of voltage and frequency variations.

Utilization Equipment.
Equipment that utilizes electric energy for electronic, electromechanical, chemical, heating, lighting, or similar purposes.

Ventilated.
Provided with a means to permit circulation of air sufficient to remove an excess of heat, fumes, or vapors.
Volatile Flammable Liquid.
A flammable liquid having a flash point below 38°C (100°F), or a flammable liquid whose temperature is above its flash point, or a Class II combustible liquid that has a vapor pressure not exceeding 276 kPa (40 psia) at 38°C (100°F) and whose temperature is above its flash point.

Voltage (of a circuit).
The greatest root-mean-square (rms) (effective) difference of potential between any two conductors of the circuit concerned.

Informational Note: Some systems, such as 3-phase 4-wire, single-phase 3-wire, and 3-wire direct current, may have various circuits of various voltages.

Voltage, Nominal.
A nominal value assigned to a circuit or system for the purpose of conveniently designating its voltage class (e.g., 120/240 volts, 480Y/277 volts, 600 volts).

Informational Note No. 1: The actual voltage at which a circuit operates can vary from the nominal within a range that permits satisfactory operation of equipment.

Informational Note No. 2: See ANSI C84.1-2011, Voltage Ratings for Electric Power Systems and Equipment (60 Hz).

Voltage to Ground.
For grounded circuits, the voltage between the given conductor and that point or conductor of the circuit that is grounded; for ungrounded circuits, the greatest voltage between the given conductor and any other conductor of the circuit.

Watertight.
Constructed so that moisture will not enter the enclosure under specified test conditions.

Weatherproof.
Constructed or protected so that exposure to the weather will not interfere with successful operation.

Informational Note: Rainproof, raintight, or watertight equipment can fulfill the requirements for weatherproof where varying weather conditions other than wetness, such as snow, ice, dust, or temperature extremes, are not a factor.

Part II. Over 1000 Volts, Nominal

Electronically Actuated Fuse.
An overcurrent protective device that generally consists of a control module that provides current sensing, electronically derived time–current characteristics, energy to initiate tripping, and an interrupting module that interrupts current when an overcurrent occurs. Electronically actuated fuses may or may not operate in a current-limiting fashion, depending on the type of control selected.

Fuse.
An overcurrent protective device with a circuit-opening fusible part that is heated and severed by the passage of overcurrent through it.

Informational Note: A fuse comprises all the parts that form a unit capable of performing the prescribed functions. It may or may not be the complete device necessary to connect it into an electrical circuit.

Controlled Vented Power Fuse.
A fuse with provision for controlling discharge circuit interruption such that no solid material may be exhausted into the surrounding atmosphere.

Informational Note: The fuse is designed so that discharged gases will not ignite or damage insulation in the path of the discharge or propagate a flashover to or between grounded members or conduction members in the path of the discharge where the distance between the vent and such insulation or conduction members conforms to manufacturer’s recommendations.

Expulsion Fuse Unit (Expulsion Fuse).
A vented fuse unit in which the expulsion effect of gases produced by the arc and lining of the fuseholder, either alone or aided by a spring, extinguishes the arc.

Nonvented Power Fuse.
A fuse without intentional provision for the escape of arc gases, liquids, or solid particles to the atmosphere during circuit interruption.

Power Fuse Unit.
A vented, nonvented, or controlled vented fuse unit in which the arc is extinguished by being drawn through solid material, granular material, or liquid, either alone or aided by a spring.

Vented Power Fuse.
A fuse with provision for the escape of arc gases, liquids, or solid particles to the surrounding atmosphere during circuit interruption.

Multiple Fuse.
An assembly of two or more single-pole fuses.
Substation.

An assemblage of equipment containing switches, interrupting devices, protection relays, buses, transformers, switchgear, motor control centers, etc. . . through which electric energy is passed for the purpose of switching or modifying characteristics. A substation is generally of such size or complexity that it incorporates one or more buses and a multiplicity of electrical equipment; it is usually the receiving point for more than one supply circuit to transform power from one voltage to another or from one system to another.

Switching Device.

A device designed to close, open, or both, one or more electrical circuits.

Circuit Breaker.

A switching device capable of making, carrying, and interrupting currents under normal circuit conditions, and also of making, carrying for a specified time, and interrupting currents under specified abnormal circuit conditions, such as those of short circuit.

Cutout.

An assembly of a fuse support with either a fuseholder, fuse carrier, or disconnecting blade. The fuseholder or fuse carrier may include a conducting element (fuse link) or may act as the disconnecting blade by the inclusion of a nonfusible member.

Disconnecting Means.

A device, group of devices, or other means whereby the conductors of a circuit can be disconnected from their source of supply.

Disconnecting (or Isolating) Switch (Disconnector, Isolator).

A mechanical switching device used for isolating a circuit or equipment from a source of power.

Interrupter Switch.

A switch capable of making, carrying, and interrupting specified currents.

Oil Cutout (Oil-Filled Cutout).

A cutout in which all or part of the fuse support and its fuse link or disconnecting blade is mounted in oil with complete immersion of the contacts and the fusible portion of the conducting element (fuse link) so that arc interruption by severing of the fuse link or by opening of the contacts will occur under oil.

Oil Switch.

A switch having contacts that operate under oil (or askarel or other suitable liquid).

Regulator Bypass Switch.

A specific device or combination of devices designed to bypass a regulator.

Statement of Problem and Substantiation for Public Comment

Action under several public inputs was made to move a number of defined terms from Articles in Chapter 5 to Chapter 1. Each of these defined terms needs to be ‘tagged’ as typically shown to reflect the origin location of this term as well as the Committee having responsibility for that term.

Additional action is needed to copy back to their original article locations, those defined terms which were moved to provide benefit and correlation for users of this Code in understanding this significant undertaking so that traditionally defined terms can be found.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-6-NFPA 70-2015
Statement: The Panel considered the relevant points made in Public Comments 1731, 1039, 199, and 300 and maintains that the definition of Accessible, Readily in the 2014 NEC is appropriate with minor revisions. The new words "other than keys" addresses the concerns about use of keys expressed in Public Comments 1731 and 199. CMP-1 is maintaining the text "to whom ready access is prerequisite" addressing concerns identified in Public Comments 1039, 1731, and 300. CMP-1 affirms that the definition as revised provides consistent and appropriate application of requirements that use the term. The new informational note provides users with clarification about how to treat supervised or controlled conditions that exist in the NEC that modify a general requirement by specific conditions that recognize controlled access, often gained by use of keys.
Accessible, Readily (Readily Accessible).

Capable of being easily reached quickly for operation, service renewal, or inspection without requiring actions such as the use of tools, the need to climb over or under, the need to remove obstacles or the use of portable ladders or similar equipment or to resort to portable ladders, and so forth.

Statement of Problem and Substantiation for Public Comment

Restore the definition as it was in the 2011 NEC. The revision made during the first draft process creates even more problems. It is not clear whether a key is considered a tool in the NEC wording, based on reviewing standard dictionary terms it is. Removing the phrase “to whom ready access is requisite” removes the permission to locate equipment behind locked doors that qualified people have access to. The term accessible is not the same term as readily accessible and is defined differently. CMP10 attempted to fix the problem made by the definition revision in the 2014 NEC but it also does not address all the issues. To address the problem described in the substantiation in the original proposal for the 2014 NEC a much better solution is to require that disconnecting means not be located behind items that need a tool to gain access. The definition of readily accessible is far reaching throughout the NEC.

Public Comment No. 199-NFPA 70-2015 [Definition: Accessible, Readily (Readily Accessible).]

Accessible, Readily (Readily Accessible).
Capable of being easily reached for operation, service, or inspection without requiring actions such as the use of tools, the need to climb over or under, the need to remove obstacles, or the use of portable ladders or similar equipment. A key that is readily available to those who require ready access to equipment shall not be considered a tool.

Statement of Problem and Substantiation for Public Comment

A key is a tool and locked equipment and rooms are not readily accessible. The rule in 110.26(F) says a locked room or locked equipment shall be considered accessible to qualified persons. It does not say that locked rooms or equipment shall be considered readily accessible.

Public Comment No. 300-NFPA 70-2015 [ Definition: Accessible, Readily (Readily Accessible). ]

**Accessible, Readily (Readily Accessible).**

**Capable of** being easily reached, **being reached quickly** for operation, **service** renewal, or inspection without requiring those to whom ready access is requisite to take actions such as the use of tools, the need to climb over or under, the need to remove obstacles, or the use of portable ladders or similar equipment.

**Statement of Problem and Substantiation for Public Comment**

I am in agreement with the statements made by Mr. Barrios and Mr. Sayler as to the removal of the phrase "to whom ready access is requisite" is more than editorial. There are installations and locations of electrical equipment where we do not want everyone to have "ready access". For example, we use locks on doors and panelboards to keep the non-qualified people out, but allow access to those qualified people who need it. In addition, the interlock on the side of a switch or combination motor starter that prevents the door from opening while the switch is in the "on" position requires a screwdriver to operate to defeat the interlock. Changing the word "renewal" to "service" may cause some unintended consequences. In addition, adding easily and removing quickly may also have some unintended consequences for an "editorial" change. I applaud CMP-1 trying to make the Code better to read, however a change in a basic definition like this one may bring unintended interpretation issues for common practices in the industry for keeping those who should not be in the electrical equipment out. In addition, those qualified people that need to be in the equipment should have quick access as needed.

**Public Comment No. 5-NFPA 70-2015 [ Definition: Associated Apparatus [as applied to Hazardous (...) ]**

**Associated Apparatus [as applied to Hazardous (Classified) Locations]. Apparatus**

Apparatus in which the circuits are not necessarily intrinsically safe themselves but that affects the energy in the intrinsically safe circuits and is relied on to maintain intrinsic safety. Such apparatus is one of the following:

1. Electrical apparatus that has an alternative type of protection for use in the appropriate hazardous (classified) location
2. Electrical apparatus not so protected that shall not be used within a hazardous (classified) location

Informational Note No. 1: Associated apparatus has identified intrinsically safe connections for intrinsically safe apparatus and also may have connections for nonintrinsically safe apparatus.

Informational Note No. 2: An example of associated apparatus is an intrinsic safety barrier, which is a network designed to limit the energy (voltage and current) available to the protected circuit in the hazardous (classified) location, under specified fault conditions.

**Statement of Problem and Substantiation for Public Comment**

This and similar revisions for other definitions relocated from Chapter 5 do not belong in Article 100. See NEC Style Manual 2.2.2.1 If it is necessary to include the text in the title referencing Article 500, that is where the definition belongs. I agree completely with CMP14 member Haywood Kines, who objected in his ballot " Definitions that are only applicable to Chapter 5 need to remain within the .2 sections within the Articles in Chapter 5 so that the information needed for the user is readily available. Relocating the definitions to Article 100 and adding the text (as applied to Hazardous (Classified) Locations) so users will understand the definitions only apply to Articles in Chapter 5 unnecessarily expands the text in Article 100 and does add any benefit to the Electrical industry using the National Electrical Code." Couldn’t have said it better myself.

**Committee Statement**

Committee Action: Rejected
Resolution: This definition, as well as the other definitions found in Articles 500 thru 516, that appear in more than one article of the NEC® have been relocated to Article 100 as mandated by Section 2.2.2.1 of the 2011 NEC® Style manual. This was done as a part of a Task Group under the direction of the Correlating Committee. Compliance with the NEC® style manual helps ensure consistency.
Authority Having Jurisdiction (AHJ).

An organization, office, or individual qualified to act, that is responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

Informational Note: The phrase “authority having jurisdiction,” or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

Statement of Problem and Substantiation for Public Comment

The NEC has a definition of qualified person so for the panel to say it does not qualify individuals is incorrect. I have change the wording from my original PI, This new text is should to be part of the AHJ definition because it also identifies and defines the AHJ has someone knowledgeable in electrical. Not having this distinction could lead to unqualified approvals creating an electrical hazard. Webster dictionary, AUTHORITY - One appealed to as an expert.

Submittal Date: Fri Sep 04 13:26:12 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The proposed revisions in Public Comment 549 are unnecessary and do not add clarity or improve usability of the current definition. Definitions shall not contain requirements as indicated in Section 2.2.2 of the NEC Style Manual. Annex H, Section 80.13 provides guidelines on credentials of authorities having jurisdiction that are typically designated by an applicable governing body. The proposed definition creates confusion in that it would imply that an entire organization or office would have to be qualified, which is beyond the intent of the current definition. This term is also defined in other NFPA standards and this revision would create a conflict and confusion the term is applied in requirements in the NEC and beyond. CMP-1 reaffirms its actions on PI 2663 which was resolved since there are circumstances where inspection or government agencies don’t exist to verify the role of the authority having jurisdiction. In those situations a property owner or designated agent may assume that role. The Code is not a document used to qualify individuals for an occupation.
Definition: Building.

A structure that is enclosed by walls and a roof and stands alone or that is separated from adjoining structures by fire walls.

Statement of Problem and Substantiation for Public Comment

The existing definition does not make sense. A billboard or pole that is not attached to a building is presently defined as a building. Buildings typically have walls and a roof.

Resolution: SR-3912-NFPA 70-2015
Combustible Dust [as applied to Hazardous (Classified) Locations].
Dust particles that are 500 microns or smaller (material passing a U.S. No. 35 Standard Sieve as defined in ASTM E 11-13, Standard Specification for Wire Cloth and Sieves for Testing Purposes), and present a fire, A finely divided combustible particulate solid that presents a flash fire hazard, or explosion hazard when dispersed, and ignited, in air, over a range of concentrations;

Statement of Problem and Substantiation for Public Comment

The committee's response to my Public Input 1311, did not address my substantiation which was based solely on the particle-size criterion in the current definition. The committee statement provided no justification for including a particle-size criterion in the definition. The particle-size criterion should be removed from the definition. The committee statement responding to my public input discussed the inclusion of oxidizing media other than air in NFPA 654's definition. I have now removed reference to oxidizing media other than air in my proposed definition, which addresses the committee response. However, whether or not material is handled in air or other oxidizing media, the 500-micron criterion is not valid as is explained below.

There is no universal particle-size criterion that determines whether a material is a combustible dust, i.e. whether it is exploisable and presents a flash fire or explosion hazard when dispersed in air. Some dusts have to be much finer than 500 microns to be exploisable in air, while others can be greater than 500 microns and still be exploisable in air. The particle-size criterion should be removed from the definition as it excludes some dust that are larger than 500 microns, exploisable, and present a hazard that may require classified electrical equipment. Incorrectly excluding these materials from the definition of combustible dust creates an unnecessary safety hazard. As described in the current informational note associated with the definition, determination of whether or not a material is a combustible dust should be based upon a test like ASTM E1226 and ISO 6184-1. These standards measure the flash fire and explosion hazards of dusts in air. Neither the informational note or committee statement provide any basis for using a particle-size criterion for the determination of explosibility.

Lastly, the particle-size criterion should be removed to create greater consistency amongst NFPA standards. The definition of combustible dust in NFPA 70 was added in the 2014 edition, and so does not have a long history in the standard. Over the last decade, an increasing number of NFPA combustible dust standards have removed particle-size criterion from definitions of combustible dust. Review of the 2014 NFPA Glossary of Terms (updated September 16, 2014) lists "combustible dust" definitions in the following standards that do not include particle-size criterion: 1, 68, 69, 77, 400, 499, 654 and the following standards that do include a particle size criterion NFPA 70 (500 microns), NFPA 5000 (420 microns). Additionally, the definition in the recently published NFPA 652 Standard on the Fundamentals of Combustible Dust does not include a particle-size criterion.

Public Comment No. 1734-NFPA 70-2015 [Definition: Cord Connector [as applied to Hazardous (Classified) Locations]]

Cord Connector [as applied to Hazardous (Classified) Locations].
A fitting intended to terminate a cord or cable to a box or similar device and reduce the strain at points of termination and may include an explosionproof, a dust-ignitionproof, or a flameproof seal.

Statement of Problem and Substantiation for Public Comment

Delete this definition.
The term "cord connector" is used to describe a wiring device in many places in the NEC. Defining it as a fitting for use in hazardous locations is problematic because it creates a situation where a term has different meanings. The rules where that term is used as a fitting should be revised to state that fitting needs to accomplish what the rule intends.

Committee Statement

Committee Action: Rejected
Resolution: Inclusion of TC-ER and TC-ER-HL as a wiring method in Articles 501, 502, 503, 505, and 506 requires a method of termination that currently is identified as a Cord Connector. The current term for this device, as used in the industry and within the product standards, is "cord connector", which should not be confused with the term also used by the wiring device industry, indicating a receptacle. The differentiation has been addressed by denoting "(as applied to hazardous (classified) locations)". The term is currently used (19) times in these articles. The panel disagrees that a term with different meaning has been created. The definition proposed for article 100 is specifically qualified for hazardous (classified) locations. The definition cannot be in Chapter 5 as this would conflict with the NEC Style Manual.
Cord Connector [as applied to Hazardous (Classified) Locations].

A fitting product intended to terminate a cord or cable to a box or similar device and reduce the strain at points of termination and may include an explosionproof, a dust-ignition proof, or a flameproof seal.

Statement of Problem and Substantiation for Public Comment

Replace text with the following: A product intended to terminate a cord or cable to a box or similar device and reduce the strain at points of termination and may include an explosionproof, a dust-ignition proof, or a flameproof seal.

While it is understood that confusion may exist with the term "cord connector" used in product standards it is felt that complete resolution resides not within the NEC, but in product standards. To reduce this impact it is strongly suggested that the term "cord fitting" be used since in fact the method of termination is incorporated often with a fitting. Therefore, the revised defined term should be as reflected above and in this comment.

Submittal Date: Sat Sep 05 13:55:07 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The term product is too broad and could inadvertently permit use of inappropriate devices to terminate the cord or cable. In addition, FR 1883 reads as follows: 336.6 Listing Requirements. Type TC cables and associated fittings shall be listed and labeled. The term fitting as defined in Article 100 is appropriate.
Cord Connector [as applied to Hazardous (Classified) Locations].
A fitting intended to terminate a cord or cable to a box or similar device and reduce the strain at points of termination and may include an explosionproof, a dust-ignitionproof, or a flameproof seal.

Statement of Problem and Substantiation for Public Comment
The committee statement indicated that this definition needed to be added for use with TC-ER and TC-ER-HL cable. However, TC-ER and TC-ER-HL are both variations on Type TC cable, which is a Chapter 3 wiring method. It is not a "cord", which would be covered under Article 400. Connectors for Type TC (and variations like TC-ER and TC-ER-HL) are required by the new language in 336.6 (FR 1833) to be listed.

Committee Statement
Committee Action: Accepted
Resolution: SR-3913-NFPA 70-2015
Statement: The definition is consistent with the use of the term “cord connector” in Chapter 5.
Public Comment No. 1520-NFPA 70-2015 [Definition: Equipment.]

**Equipment.**
A general term, including fittings, devices, appliances, luminaires, apparatus, machinery, and the like used as a part of, or in connection with, an electrical installation.

**Informational Note:** In addition to the items listed in the definition, equipment also describes air conditioning units, power outlets (such as recreational vehicle site supply equipment or marine power outlets), transformers, and other enclosures that contain electrical products.

**Statement of Problem and Substantiation for Public Comment**
FR-10, which added a new Informational Note, should not have been accepted.
The addition of an Informational Note to the definition of "equipment" in order to provide additional examples to the growing laundry list of examples is not necessary. The definition already includes the phrase "and the like" to cover other examples. The proposed Informational Note adds no additional clarity to the existing examples and does not additionally clarify what is or what is not a structure, which was the original intent of the FR.

Submittal Date: Tue Sep 08 14:22:11 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: Requirements for these devices have been removed from Articles 210 and 215, thus the definition is unnecessary.
Ground-Fault Circuit Interrupter, Special-Purpose (SPGFCI).

A device intended for the protection of personnel that functions to de-energize a circuit or portion of a circuit within an established period of time when a current to ground exceeds the values established for Class C, D, and E devices.

Informational Note: Classes C, D, and E ground-fault circuit interrupters trip when the current to ground is 20 mA or higher and do not trip when the current to ground is less than 15 mA. For further information, see UL 943C, Outline of Investigation for Special Purpose Ground-Fault Circuit Interrupters.

Statement of Problem and Substantiation for Public Comment

This change is to add a hyphen to "special purpose" to be consistent with how SPGFCIs were referenced in FR-347.

Committee Statement

Committee Action: Rejected
Resolution: Requirements for these devices have been removed from Articles 210 and 215, thus the definition is unnecessary.
Ground-Fault Circuit Interrupter, Special Purpose (SPGFCI):
A device intended for the protection of personnel that functions to de-energize a circuit or portion of a circuit within an established period of time when a current to ground exceeds the values established for Class C, D, and E devices.

Informational Note: Classes C, D, and E ground-fault circuit interrupters trip when the current to ground is 20 mA or higher and do not trip when the current to ground is less than 15 mA. For further information, see UL 943C, Outline of Investigation for Special Purpose Ground-Fault Circuit Interrupters.

Statement of Problem and Substantiation for Public Comment
Due to the unacceptable language proposed in FR 347, the addition of this definition is not appropriate for the installation of Special Purpose Ground-Fault Circuit Interrupters in 210.8(B) [FR 347].

Statement: Requirements for these devices have not been added to Articles 210 and 215, thus the definition is unnecessary.
Public Comment No. 497-NFPA 70-2015 [Definition: In Sight From (Within Sight From, Within Sight).]

In Sight From (Within Sight From, Within Sight).
Where this Code specifies that one equipment shall be “in sight from,” “within sight from,” or “within sight of,” and so forth, from or to another equipment, the specified equipment is to be visible and not more than 15 m (50 ft) distant from the other.

Statement of Problem and Substantiation for Public Comment

In response to your Committee Statement, use of the terms that are being defined that are in the definition is an existing condition and was not a part of my Public Input.
As I recall, this definition formerly contained similar words that were removed some time ago. The present definition reads awkwardly at best.
The definition is incomplete without the additional words that are proposed. Please add them.

<td>358.6 requires that EMT fittings are to be listed, the UL Guide Information indicates that the UL symbol is on the product and the Mark of UL is on the smallest unit container in which the product is packaged.</td>
<td></td>
</tr>
</tbody>
</table>

Statement of Problem and Substantiation for Public Comment

Based on CMP1’s comment to PI 881; “Labeling of listed equipment is not possible in all cases or conditions such as if products are too small to be labeled or for some severe environmental conditions” and CMP 8’s comment to PI 895; “Some Listed products are marked or require markings on the smallest shipping package” it appears this informational note may be necessary. Both the concerns of CMP1 and CMP 8 appear to be in agreement with the substantiation of PI 881.

By adding this informational note, it explains to an AHJ that even though a section of the NEC may require a product to be labeled, it is acceptable to have the label, symbol, or other identifying mark applied to the packaging or a tag in some instances. Without this informational note, if interpreted verbatim by the AHJ, this definition requires the label, symbol, or other identifying mark to be attached to the equipment or material. Without this informational note, AHJ’s may not accept a label that is affixed to the packaging where permitted by the certification organization.

City: 
State: 
Zip: 
Submittal Date: Thu Sep 03 20:36:54 EDT 2015

Committee Statement
Committee Action: Rejected but held
Resolution: The inconsistent actions on Public Inputs to globally change the term “listed or labeled” to “listed and labeled” resulted in multiple inconsistencies through the NEC and created conflicts with other Codes and Standards that use the term. CMP-1 understands that the NEC Correlating Committee took action to develop a first revision that restores the NEC rules using the term listed or labeled to how those rules appeared in the 2014 edition. CMP-1 also understands that the NEC Correlating Committee has formed a Task Group to globally review the use of the term “listed or labeled” throughout the NEC and determine a simplified solution that addresses the terms listed, labeled, and their associated informational notes. The Task Group is to address the concerns and input from multiple qualified electrical testing laboratories and work toward a simple solution that resides within Article 100 and perhaps Article 110. The work of that task group is just getting started and may include proposed revisions to these existing definitions and associated informational notes. CMP-1 recognizes it is premature to incorporate the proposed revisions and informational note at this time.
Receptacle.
A contact device installed at the outlet for the connection of an attachment plug or attachment fitting. A single receptacle is a single contact device with no other contact device on the same yoke. A multiple receptacle is two or more contact devices on the same yoke.

Statement of Problem and Substantiation for Public Comment

This Comment seeks to further modify the definition of "receptacle" that was modified in First Revision No. 5114. This change reflects the suggestion in the CMP 18 ballot comment where it was noted that the definition of "receptacle" should've been expanded further, as follows:

"...should have been expanded to account for changes in technology that would use the receptacle to accept things beyond the classical attachment plug. As was demonstrated, electrical connectors other than attachment plugs as defined in Article 100 should be allowed to use the receptacle."

Additionally, new text was proposed and approved for 314.27(E) by CMP 9 in FR 2411 that read as follows:

(E) Separable Attachment Fittings. Outlet boxes shall be permitted to support listed locking support and mounting receptacles used in combination with compatible attachment fittings designed for the support of equipment covered within and subject to all weight and orientation limits contemplated by the listing. Where such fittings are used, the equipment mounted shall comply with 314.27(A) through (D) as applicable. Where the supporting receptacle is installed within a box, it shall be included in the fill calculation covered in 314.16(B)(4).

CMP 9 has appropriately used the word "receptacle" in the context of accepting an attachment fitting. The definition of receptacle needs to be modified to coordinate with this new section 314.27(E). There is also a complementary public comment to add a new definition of attachment fitting that is also needed for the same reasons.

Statement: This wording is reflective of CMP 9 action at the First Draft Meeting and clarifies our intent for the definition. This change addresses the concern noted by the Correlating Committee in PC # 1745
Public Comment No. 428-NFPA 70-2015 [Definition: Substation.]

Substation.
An assemblage of equipment containing (e.g., switches, interrupting devices, protection relays, circuit breakers, buses, transformers, switchgear, motor control centers, etc., and transformers) through which electric energy is passed for the purpose of switching, distribution, switching, or modifying characteristics. A substation is generally of such size or complexity that it incorporates one or more buses and a multiplicity of electrical equipment; it is usually the receiving point for more than one supply circuit to transform power from one voltage to another or from one system to another, its characteristics.

Statement of Problem and Substantiation for Public Comment

The wording of this definition as presented in the First Draft does not reflect the final action of CMP 9 on the revision. Numerous comments submitted by Panel Members during balloting highlight this issue, as well as the Committee Statement which is inconsistent with the First Revision as recorded. This Public Comment is intended to restore the Code text to the panel action established during the First Revision meeting.

Resolution: SR-2413-NFPA 70-2015
Statement: This wording is reflective of CMP 9 action at the First Draft Meeting and clarifies our intent for the definition. This change addresses the concern noted by the Correlating Committee in PC # 1745.
Public Comment No. 687-NFPA 70-2015 [Definition: Substation.]

Substation.
An assemblage of equipment containing switches, interrupting devices, protection relays, buses, transformers, switchgear, motor control centers, etc, through which electric energy is passed for the purpose of switching or modifying characteristics. A substation is generally of such size or complexity that it incorporates one or more buses and a multiplicity of electrical equipment; is usually the receiving point for more than one supply circuit to transform power from one voltage to another or from one system to another.
Add Informational Note: While substations typically contain voltages greater than 1000V, voltages less than 1000V may be present.
Add definition of Power Distribution Center in Part I of Art. 100 to replace the removal of Substation.

Additional Proposed Changes

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PDC_definition.docx</td>
<td>This is a new definition to cover those instances where Substation doesn't apply due to voltage level.</td>
</tr>
</tbody>
</table>

Statement of Problem and Substantiation for Public Comment

I was part of the task group that removed the term "Substation" from Part I. While I'm in agreement with this change, this has left a void for large enclosures, similar to a building and substations, that are found throughout the world containing voltages less than 1000V.
If "Substation" is now going to mean that voltages greater than 1000V must exist within the enclosure or outdoor installation, then we need to fill the void left by removing the term from Part I of Art. 100.
There are "Power Distribution Centers" also known in the industry as substations that only contain voltages less than 1000V. Also, it's a little misleading by placing the term "Substation" in Part II, as there are typically other voltages present such as SCADA, DCS, Instrumentation, station control power, lighting and HVAC circuits that are less than 1000V. Adding the informational note to the new definition of Substation in Part II would clarify that voltages less than 1000V may be present in addition to the medium and high voltages.

Organization: Fluor Enterprises, Inc.
Affiliation: Associated Builders and Contractors
Street Address: 
City: 
State: 
Zip: 
Submittal Date: Thu Sep 17 09:53:46 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: CMP 9 does not agree with adding a definition for “Power Distribution Centers” since this is not a term used in the Code (as required by paragraph 2.2.2.1 of the NEC Style Manual). In addition, the Informational Note is not needed since the definition does not stipulate that substations contain circuits with specific voltages, and such a limitation would not be appropriate since definitions should not include requirements. See SR 2413.
Definitions (100): Fitting... to Garage...

Fitting.
An accessory such as a locknut, bushing, or other part of a wiring system that is intended primarily to perform a mechanical rather than an electrical function.

Flood Definitions. The following definitions apply to Article 110.11 (B).

(Note: The followings sources cited in brackets [ ] are included information for only and are intended to be used by the Committee considering these revisions. They are not intended to be made part of the Code.):

Base Flood. The flood having a 1 percent chance of being equaled or exceeded in any given year. [Source NFPA 5000]

Base Flood Elevation (BFE). The elevation of the base flood, including wave height, relative to the datum specified on a jurisdiction’s flood hazard map. [Source NFPA 5000]

Design Flood. The greater of either (1) the base flood or (2) the flood so designated by the jurisdiction as its regulatory flood, with a 1 percent chance, or less, of being equaled or exceeded in any given year. [Source NFPA 5000]

Design Flood Elevation (DFE). The elevation of the design flood, including wave height, relative to the datum specified on a jurisdiction’s flood hazard map. [Source NFPA 5000]

Dry Floodproofing. A combination of design modifications that results in a building or structure, including the attendant utility and sanitary facilities, being watertight, with walls substantially impermeable to the passage of water, and with structural components having the capacity to resist loads and load combinations associated with the design flood. [Source NFPA 5000]

Flood Hazard Area. The greater of either (1) the special flood hazard area shown on the flood insurance rate map or (2) the area subject to flooding during the design flood and shown on a jurisdiction’s flood hazard map, or otherwise legally designated. [Source NFPA 5000]

Special Flood Hazard Area. The land area subject to flooding by the base flood, and depicted on the flood insurance rate map or other flood hazard map as Zone A, Zone AE, Zone A1-30, Zone A99, Zone AO, Zone AR, Zone AH, Zone V, Zone VE, Zone V1-30, or Zone VO. (See also 39.2.1.3, Coastal A Zone.) [Source NFPA 5000]

Garage.
A building or portion of a building in which one or more self-propelled vehicles can be kept for use, sale, storage, rental, repair, exhibition, or demonstration purposes.

Informational Note: For commercial garages, repair and storage, see Article 511.

Statement of Problem and Substantiation for Public Comment

These definitions are needed for PC-1248-NFPA-70-2015 which revises Article 110.11 Deteriorating Agents

Attachment Fitting. A fitting that by insertion in a receptacle establishes a connection between the conductors of the utilization device and the conductors connected permanently to the receptacle.

Statement of Problem and Substantiation for Public Comment

New text was proposed and approved for 314.27(E) by CMP 9 in FR 2411 that read as follows:

(E) Separable Attachment Fittings. Outlet boxes shall be permitted to support listed locking support and mounting receptacles used in combination with compatible attachment fittings designed for the support of equipment covered within and subject to all weight and orientation limits contemplated by the listing. Where such fittings are used, the equipment mounted shall comply with 314.27(A) through (D) as applicable. Where the supporting receptacle is installed within a box, it shall be included in the fill calculation covered in 314.16(B) (4).

CMP 9 has appropriately used the word “receptacle” in the context of accepting an attachment fitting. The definition of attachment fitting needs to be added to coordinate with this new section 314.27(E). The definition for “attachment fitting” was also previously submitted in PI 4316. There is also a complementary Public Comment to add a revised definition of “receptacle” that is also needed for the same reasons.

Submittal Date: Tue Sep 15 13:18:34 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: An attachment fitting is not a stand-alone listed device but rather is a component in a listed assembly such as a luminaire or ceiling fan, therefore does not need to be defined.
Dormitory. Any occupancy containing a number of beds with common areas and bathroom facilities where people are housed temporarily.

Statement of Problem and Substantiation for Public Comment

Requirements for AFCI protection in 210.12 and tamper-resistant receptacles in 406.12 now apply to dormitories. Without an NEC definition of the word “dormitory” installers and inspectors find this section problematic. Perhaps the code-making panel will provide some guidance on whether this requirement should apply to bunkhouses, church camps, summer-camp cabins, lodges, homeless shelters, etc., which will greatly help with the application of the rule. Accepting the original proposal for the 2014 NEC the panel specifically removed the word “college” from the new AFCI requirement, however many dictionaries specifically reference “colleges” in their definition of the term. The lack of a definition appears to make broad application of those rules appropriate.

Submittal Date: Fri Sep 25 15:24:40 EDT 2015

Committee Statement

Committee Action: Rejected but held
Resolution: The proposed definition of “Dormitory” is new material that has not had public review and is a violation of sections 4.4.4.2 and 4.4.8.3 of the Regulations Governing Development of Standards. The definition is being held for the 2020 NEC development process. CMP-1 requests that this PC be sent to CMP-2 and CMP-18 for information. This new definition will likely fall under the purview of CMP 2. It should be noted that there is a definition of dormitory in NFPA 5000.
**Equipment Ground-Fault Protective Device (EGFPD).**
A device identified for use as an Equipment Ground-Fault Protective Device or EGFPD that operates to disconnect the electric circuit from the source of supply when ground-fault current exceeds the ground-fault pick-up level marked on the device.

Informational Note: Ground-fault current pick-up level of equipment ground-fault protective devices is adjustable from 6 to 100 mA.

**Statement of Problem and Substantiation for Public Comment**
This new definition is needed for a proposed change to Article 590.6(B) that was submitted to CMP 3.

**Related Public Comments for This Document**

- **Submittal Date:** Sat Sep 12 16:41:19 EDT 2015

**Committee Statement**
- **Committee Action:** Rejected
- **Resolution:** Action on the proposed definition belongs to Panel 1 and is predicated on an action to be taken by Panel 3 (covering Art 590). In any case, from the perspective of Panel 17 the definition is confusing and unnecessary as it is difficult to distinguish it from the existing Art 100 definition of Ground-Fault Protection of Equipment (GFPE) and it appears to represent a subset of GFPE already covered by the GFPE definition.
Approval.
The conductors and equipment required or permitted by this Code shall be acceptable only if approved. Approval shall not extend to the internal wiring of a manufactured or listed equipment.

Informational Note: See 90.7, Examination of Equipment for Safety, and 110.3, Examination, Identification, Installation, and Use of Equipment. See definitions of Approved, Identified, Labeled, and Listed.

Statement of Problem and Substantiation for Public Comment

Please read 300.1(B) which is contrary to the panels statement, this is not within the AHJ's purview, only the installation of this product is approved by the AHJ following 110.3(B) not the internal wiring which has already been delegated to a third party inspection service.

300.1 ( B) Integral Parts of Equipment. The provisions of this article are not intended to apply to the conductors that form an integral part of equipment, such as motors, controllers, motor control centers, or factory assembled control equipment or listed utilization equipment.

However the placement and labeling instructions for the equipment are within the AHJ approval

Resolution: The second paragraph of Section 90.7 already addresses the concerns expressed in PI 2890. The proposed text does not enhance clarity or usability of the NEC.
110.3 Examination, Identification, Installation, and Use of Equipment.

(A) Examination.

In judging equipment, considerations such as the following shall be evaluated:

(1) Suitability for installation and use in conformity with the provisions of this Code

   Informational Note

No. 1

Equipment may be new, reconditioned, refurbished, or remanufactured. Informational Note No. 2:

Suitability of equipment use may be identified by a description marked on or provided with a product to identify the suitability of the product for a specific purpose, environment, or application. Special conditions of use or other limitations and other pertinent information may be marked on the equipment, included in the product instructions, or included in the appropriate listing and labeling information. Suitability of equipment may be evidenced by listing or labeling.

(2) Mechanical strength and durability, including, for parts designed to enclose and protect other equipment, the adequacy of the protection thus provided

(3) Wire-bending and connection space

(4) Electrical insulation

(5) Heating effects under normal conditions of use and also under abnormal conditions likely to arise in service

(6) Arcing effects

(7) Classification by type, size, voltage, current capacity, and specific use

(8) Other factors that contribute to the practical safeguarding of persons using or likely to come in contact with the equipment

(B) Installation and Use.

Listed or labeled equipment shall be installed and used in accordance with any instructions included in the listing or labeling.

(C) Listed.

Where equipment, conductors, raceways, devices, fittings and other materials are required to be listed elsewhere in this code, the listing shall be compatible with product listing documents recognized within the country, state, and/or municipality of the installation.

Statement of Problem and Substantiation for Public Comment

Informational Note is existing text.

The requested changes from PI 2839 should have been incorporated into a First Revision.

The North American electrical system is the safest in the world, built upon the coordinated workings of: 1) Product standards aligned with; 2) the Installation Code; enforced by; 3) a Strong inspection community. Weakening of ANY of these basic tenants threatens the overall safety of our electrical system.

As the submitter of PI 2839 stated, there are increasing requests for equipment which has not been 3rd party evaluated to verify its performance, nor its alignment with the requirements of the NEC. This puts a tremendous burden upon the AHJ to judge and determine its applicability. The requested change will give the AHJ much needed clarity to assure that Listed equipment is judged in accordance with requirements aligned to the NEC. This is critical to the safe installation & operation of NEMA equipment.

The committee's resolution statement to PI 2839 refers to Section 90.7, which indeed has some overall introduction statements for "Examination of Equipment for Safety." It must also be noted that in the Informational Note 1 to 90.7, it indeed refers over to 110.3 for the requirements. Hence the location suggested by the submitter is acceptable. The additional committee comments about testing laboratories are non-germane as they are not mentioned in PI 2839. Maybe the intent was misunderstood.
Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-2-NFPA 70-2015
Statement: In exercising their approving authority in 90.4, the AHJ depends on listing and product certification as the most common basis for approvals of installations in accordance with the National Electrical Code. The additional list item (C) Listing provides clarification about requirements for listing (product certification) being accomplished by qualified electrical testing laboratories and that the product testing and certification process is in accordance with appropriate product standards.

The new informational note provides users with information about a list of nationally recognized testing laboratories that meet or exceed OSHA criteria. Product listing (certification) is the most common basis for AHJ approvals and the product listing must meet or exceed the minimum product safety requirements developed by recognized standards development organizations.

With regard to PC 814, Panel 1 did not agree that Informational Note 1 should be deleted. The committee reaffirms the need for the new Informational Note No. 1 following 110.3(A) to clarify that the general term equipment can apply to new equipment and also used, refurbished, or reconditioned, remanufactured equipment.

With regard to PC 949, the intent of the submitter is met with the acceptance of SR 2.
Public Comment No. 938-NFPA 70-2015 [Section No. 110.3]

110.3 Examination, Identification, Installation, and Use, and Listing (Product Certification), of Equipment.

(A) Examination.

In judging equipment, considerations such as the following shall be evaluated:

1. Suitability for installation and use in conformity with the provisions of this Code

   Informational Note No. 1: Equipment may be new, reconditioned, refurbished, or remanufactured.

   Informational Note No. 2: Suitability of equipment use may be identified by a description marked on or provided with a product to identify the suitability of the product for a specific purpose, environment, or application. Special conditions of use or other limitations and other pertinent information may be marked on the equipment, included in the product instructions, or included in the appropriate listing and labeling information. Suitability of equipment may be evidenced by listing or labeling.

2. Mechanical strength and durability, including, for parts designed to enclose and protect other equipment, the adequacy of the protection thus provided

3. Wire-bending and connection space

4. Electrical insulation

5. Heating effects under normal conditions of use and also under abnormal conditions likely to arise in service

6. Arcing effects

7. Classification by type, size, voltage, current capacity, and specific use

8. Other factors that contribute to the practical safeguarding of persons using or likely to come in contact with the equipment

(B) Installation and Use.

Listed or labeled equipment shall be installed and used in accordance with any instructions included in the listing or labeling.

(C) Listing. Product testing, evaluation, listing (product certification) shall be performed by recognized qualified electrical testing laboratories and shall be in accordance with applicable product standards recognized as achieving equivalent and effective safety for equipment installed to comply with this Code.

Informational Note: The Occupational Safety and Health Administration recognizes qualified electrical testing organizations (NRTLs) that perform evaluations, testing, and certification of certain products to ensure that they meet the requirements of both the construction and general industry OSHA electrical standards. If the listing (product certification) is done under a qualified electrical testing laboratory program, this listing mark signifies that the tested and certified the product complies with the requirements of one or more appropriate product safety test standards.

Statement of Problem and Substantiation for Public Comment

In exercising their approving authority in 90.4, the AHJ depends on listing and product certification as the most common basis for approvals of installations in accordance with the National Electrical Code. The additional list item (C) Listing provides clarification about requirements for listing (product certification) being accomplished by qualified electrical testing laboratories and that the product testing and certification process is in accordance with appropriate product standards. The new informational note provides users with information about a list of nationally recognized testing laboratories that meet or exceed OSHA criteria. Product listing (certification) is the most common basis for AHJ approvals and the product listing must meet or exceed the minimum product safety requirements developed by recognized standards development organizations.

### Committee Statement

**Committee Action:** Rejected but see related SR

**Resolution:** SR-2-NFPA 70-2015

**Statement:**

In exercising their approving authority in 90.4, the AHJ depends on listing and product certification as the most common basis for approvals of installations in accordance with the National Electrical Code. The additional list item (C) Listing provides clarification about requirements for listing (product certification) being accomplished by qualified electrical testing laboratories and that the product testing and certification process is in accordance with appropriate product standards. The new informational note provides users with information about a list of nationally recognized testing laboratories that meet or exceed OSHA criteria. Product listing (certification) is the most common basis for AHJ approvals and the product listing must meet or exceed the minimum product safety requirements developed by recognized standards development organizations.

With regard to PC 814, Panel 1 did not agree that Informational Note 1 should be deleted. The committee reaffirms the need for the new Informational Note No. 1 following 110.3(A) to clarify that the general term equipment can apply to new equipment and also used, refurbished, or reconditioned, remanufactured equipment.

With regard to PC 949, the intent of the submittor is met with the acceptance of SR 2.
Public Comment No. 1366-NFPA 70-2015 [Section No. 110.3(A)]

(A) Examination.

In judging equipment, considerations such as the following shall be evaluated:

1. Suitability for installation and use in conformity with the provisions of this Code

   Informational Note No. 1: Equipment may be new, reconditioned, refurbished, or remanufactured.

   Informational Note No. 2: Suitability of equipment use may be identified by a description marked on or provided with a product to identify the suitability of the product for a specific purpose, environment, or application. Special conditions of use or other limitations and other pertinent information may be marked on the equipment, included in the product instructions, or included in the appropriate listing and labeling information. Suitability of equipment may be evidenced by listing or labeling.

2. Mechanical strength and durability, including, for parts designed to enclose and protect other equipment, the adequacy of the protection thus provided

3. Wire-bending and connection space

4. Electrical insulation

5. Heating effects under normal conditions of use and also under abnormal conditions likely to arise in service

6. Arcing effects

7. Classification by type, size, voltage, current capacity, and specific use

8. Other factors that contribute to the practical safeguarding of persons using or likely to come in contact with the equipment

Statement of Problem and Substantiation for Public Comment

The Correlating Committee note directing the committee to rewrite the language to remove permissive language in Informational Note 1 is unclear. It appears that the Note is indicating that the panel should remove the word "may", although the style manual does not prohibit, or in fact mention, the use of the word "may" when used in an informational note. The term "may" is only prohibited in mandatory rules, and informational notes are prohibited from containing any rules whatsoever. The wording accepted in FR-31 seems clear, informs the code user about available equipment, and complies with the style manual. Interestingly, IN 2 contains the word "may" three times.

Committee Action: Rejected
Resolution: The Public Comment did not comply with Section 4.4.4.3(c) of the “Regulations Governing the Development of NFPA Standards” which requires that the Public Comment include the wording to be added, revised, or deleted.
Public Comment No. 1529-NFPA 70-2015 [Section No. 110.3(A)]

(A) Examination.
In judging equipment, considerations such as the following shall be evaluated:

1. Suitability for installation and use in conformity with the provisions of this Code

   Informational Note No. 1: Equipment may be new, reconditioned, refurbished, or remanufactured.

2. Suitability of equipment use may be identified by a description marked on or provided with a product to identify
   the suitability of the product for a specific purpose, environment, or application. Special conditions of use or other
   limitations and other pertinent information may be marked on the equipment, included in the product instructions, or
   included in the appropriate listing and labeling information. Suitability of equipment may be evidenced by listing or
   labeling.

3. Mechanical strength and durability, including, for parts designed to enclose and protect other equipment, the adequacy of
   the protection thus provided

4. Wire-bending and connection space

5. Electrical insulation

6. Heating effects under normal conditions of use and also under abnormal conditions likely to arise in service

7. Arcing effects

8. Classification by type, size, voltage, current capacity, and specific use

9. Other factors that contribute to the practical safeguarding of persons using or likely to come in contact with the equipment

Statement of Problem and Substantiation for Public Comment

FR-31, which added new Informational Note 1, should not have been accepted. The committee statement to FR-31 provided no substantiation for the change. The addition of this Informational Note may have unintended consequences and be misinterpreted to indicate that the Code is retroactive to reconditioned, refurbished and remanufactured equipment.

Committee Statement

Committee Action: Rejected
Resolution: Panel 1 concludes that the text of First Revision 31 is not in violation of the NEC Style Manual.
(C) Listed. Where equipment, conductors, raceways, devices, fittings and other materials are required to be listed elsewhere in this code, the listing shall be compatible with applicable product standards recognized within the country, state, and/or municipality of the installation.

Statement of Problem and Substantiation for Public Comment

CMP-1 resolved PI 2839 with a statement that essentially agreed with the proposed revision. As the original submitter of PI 2839, I have submitted a similar public comment for CMP-1 to reconsider.

The statement to resolve this proposed revision states that section 90.7 addresses the concerns of the submitter. That is not true. The intent of this new first level subdivision is to simply require that the “applicable” listing or product standard be applied. This is a very simple concept that is essential for proper application of the NEC.

We all know that in order to achieve safe electrical installations in the U.S. we need three things. It is a three-legged stool, remove one leg and you have a “house of cards” that falls down in spite of all of your efforts.

One, we need a comprehensive “installation code” that is practical, easy to read and enforceable. We have that in the NEC.

Two, we need robust “product standards” that literally “build-in” required safety features for equipment required in the “installation code.” We have that in the existing U.S. product standards.

Three, we need comprehensive electrical inspections that enforce the “installation code” and the applicable “product standards”. We do have excellent inspections in the U.S. The question is “which listing” or “which product standard” should apply?

This proposed new first level subdivision accomplishes several things.

First, it ensures that the “applicable” listing or product standard is applied. Product standards will differ from country to country. If there is a U.S. product standard that given equipment must meet in the U.S. to be listed, then it makes sense that only products listed to the U.S. product standard be permitted. To do otherwise eliminates the “built-in” safety requirements and creates a “wild, wild west” atmosphere.

Second, this revision will promote adoption in other countries that have their own product standards.

Third, this revision enhances safety by ensuring the applicable listing is applied.

Fourth, this is essential for the authority having jurisdiction. This revision provides clarity, and assists the AHJ in enforcement of the applicable listing.

OSHA does recognize various NRTL’s. It is imperative to note that OSHA will require the applicable U.S. product standard and listing be applied where one exists.

This proposed revision aids the enforcement community, ensures “applicable” listings are applied, makes the NEC work for adoption by other countries and significantly improves safety by requiring the applicable listing or product standard be applied.

The original substantiation for PI 2839 is located below for your information:

The NEC presently has many individual requirements that particular products be listed. When these listed products are required, it is important that they are properly evaluated, and that they be listed to product standards that are compatible with this code. From a safety viewpoint it is also critical that the listing organization have a follow up surveillance program in place to assure continued compliance. The electrical industry has seen requests to accept CE marked equipment, which merely indicates a one-time, “self-certified” declaration by the manufacturer to European regulations which have not been evaluated to meet the requirements of this code. In some cases tremendous political pressure on an AHJ to accept equipment that is labeled and self certified outside of the United States. This can create many serious safety issues including but not limited to; color code requirements in the NEC that are ignored by the IEC, and overcurrent protective device opening times for similar devices may be significantly expanded. Both the North American system and the European systems work very well when implemented independently of each other. However, they cannot be mixed together and still achieve the necessary level of safety to protect persons and property from the hazards of electricity. It is imperative to clarify this with a requirement in the NEC and a new second level subdivision in 110.3 is the appropriate location to get it done.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-2-NFPA 70-2015
Statement: In exercising their approving authority in 90.4, the AHJ depends on listing and product certification as the most common basis for approvals of installations in accordance with the National Electrical Code. The additional list item (C) Listing provides clarification about requirements for listing (product certification) being accomplished by qualified electrical testing laboratories and that the product testing and certification process is in accordance with appropriate product standards. The new informational note provides users with information about a list of nationally recognized testing laboratories that meet or exceed OSHA criteria. Product listing (certification) is the most common basis for AHJ approvals and the product listing must meet or exceed the minimum product safety requirements developed by recognized standards development organizations.

With regard to PC 814, Panel 1 did not agree that Informational Note 1 should be deleted. The committee reaffirms the need for the new Informational Note No. 1 following 110.3(A) to clarify that the general term equipment can apply to new equipment and also used, refurbished, or reconditioned, remanufactured equipment.

With regard to PC 949, the intent of the submitter is met with the acceptance of SR 2.
Public Comment No. 531-NFPA 70-2015 [Section No. 110.3(B)]

(B) Installation and Use.
Listed or listed and labeled equipment shall be installed and used in accordance with any instructions included in the listing or listing and labeling.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacturer remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

Committee Statement

Committee Action: Rejected but held

Resolution: The inconsistent actions on Public inputs to globally change the term “listed or labeled” to “listed and labeled” resulted in multiple inconsistencies through the NEC and created conflicts with other Codes and Standards that use the term. CMP-1 understands that the NEC Correlating Committee took action to develop a first revision that restores the NEC rules using the term listed or labeled to how those rules appeared in the 2014 edition. CMP-1 also understands that the NEC Correlating Committee has formed a Task Group to globally review the use of the term “listed or labeled” throughout the NEC and determine a simplified solution that addresses the terms listed, labeled, and their associated informational notes. The Task Group is to address the concerns and input from multiple qualified electrical testing laboratories and work toward a simple solution that resides within Article 100 and perhaps Article 110. The work of that task group is just getting started and may include proposed revisions to these existing definitions and associated informational notes. CMP-1 recognizes it is premature to incorporate the proposed revisions and informational note at this time.
110.11 Deteriorating Agents.

(A) Unless identified for use in the operating environment, no conductors or equipment shall be located in damp or wet locations; in locations prone to flooding; where exposed to gases, fumes, vapors, liquids, or other agents that have a deteriorating effect on the conductors or equipment; or where exposed to excessive temperatures.

Informational Note No. 1: See 300.6 for protection against corrosion.

Informational Note No. 2: Some cleaning and lubricating compounds can cause severe deterioration of many plastic materials used for insulating and structural applications in equipment.

Equipment not identified for outdoor use and equipment identified only for indoor use, such as “dry locations,” “indoor use only,” “damp locations,” or enclosure Types 1, 2, 5, 12, 12K, and/or 13, shall be protected against damage from the weather during construction.

Informational Note No. 3: See Table 110.28 for appropriate enclosure-type designations.

(B) Installations in Flood Hazard Areas. For installations in Flood Hazard Areas, conductors and equipment shall be elevated to or above the Base Flood Elevation plus one foot (BFE plus 1) or the Design Flood Elevation (DFE) whichever is higher.

Exception No. 1: Conductors and equipment shall be permitted to be located below the elevation specified above provided they are designed and installed to prevent flood waters from entering or accumulating within components during design flood conditions and all equipment is designed and installed to resist flood loads resulting from inundation to the elevation specified above.

Exception No. 2: Where conductors and equipment are suitable for submerged applications and are designed and installed to resist flood loads resulting from inundation to the elevation specified above.

Exception No. 3: When located in areas protected by dry floodproofing to the elevation specified above.

Exception No. 4: Where allowed by Article 682.

Informational Note No. 4: Minimum flood provisions are provided in NFPA 5000-2015 Building Construction and Safety Code, the International Building Code (IBC), and the International Residential Code for One- and Two-Family Dwellings (IRC).

Statement of Problem and Substantiation for Public Comment

Background (Note - this text is included for substantiation - a pdf of it has been attached - The proponent believes that the pdf may be clearer and easier for the Committee to read)

This language included in these Public Inputs was presented in October 2014 as Public Input 4142 and Public Input 4144. PI 4142 created a new sub-section (C) of Art 110.3 Installations in Flood Hazard Areas. PI 4144 added new definitions into Article 100 for terms used in the new Art 110.3 (C).

PI 4142 included the following substantiation for the proposed Art 110.3(C) language

1. This change includes the minimum flood provisions that already exist in the 2015 Edition of NFPA 5000 Building Construction and Safety Code, the 2015 International Building Code (IBC) and the 2015 International Residential Code for One- and Two-Family Dwellings (IRC).

2. The change will make the minimum flood provisions more assessable to practicing electrical engineers, electrical inspectors and electricians.

Code Making Panel (CMP-1), the Committee responsible for Articles 100 and 110, chose not to incorporate the proposed material. Rather, they developed FR-35 which added the following Informational Note 4 to Art 110-11 Deteriorating Agents.

“Informational Note No. 4: Minimum flood provisions are provided in NFPA 5000 -2015 Building Construction and Safety Code, the International Building Code (IBC), and the International Residential Code for One- and Two-Family Dwellings (IRC).”
In their reason statement, CMP-1 stated the new Informational Note was more appropriate in Article 110.11 Deteriorating Agents than in the originally proposed Article 110.3 Examination, Identification, Installation, and Use of Equipment. They also stated the following two reasons for not incorporating PI 4142.

1. The proposed requirement would apply generally and may cause conflict with other requirements throughout the Code. And.
2. Accessibility to information alone is not sufficient substantiation for inclusion of a requirement.

PI-4144 was rejected since, without PI-4142 being incorporated, the proposed flood definitions were no longer needed.

The proponent agrees with the Committee on the placing the new language in Article 110.11 Deteriorating Agents instead of creating a new Article 110.3(C) but disagrees with the committee’s reason statement for disapproving the PI-4142. The proponent is submitting two new PIs for the 1st Draft of the 2017 NEC which are nearly identical to those submitted previously except they request changes to Art 110.11 instead of Art 110.3 and they include responses to the Committee’s reasons for disapproval. The committee listed two reasons for disapproval. In the response, the proponent has considered the issue of the general nature of the proposed language and the issue of potential conflict with other portions of the code separately.

Reason for Rejection #1a General Nature of the Proposed Requirements:

The PI proposes the following language be introduced into Art 110

110.11 Deteriorating Agents. (A) Unless identified for use in the operating environment, no conductors or equipment shall be located in damp or wet locations; in locations prone to flooding; where exposed to gases, fumes, vapors, liquids, or other agents that have a deteriorating effect on the conductors or equipment; or where exposed to excessive temperatures.

“(B) Installations in Flood Hazard Areas. For installations in Flood Hazard Areas, conductors and equipment shall be elevated to or above the Base Flood Elevation plus one foot (BFE 1) or the Design Flood Elevation (DFE) whichever is higher.”

Proponent’s Response – The proponent wishes to split the existing Article 110.11 Deteriorating Agents into two subsections “(A)” and “(B)”. Subsection A would remain general and like the existing language would apply to all installations. The new subsection (B) would not be general in nature and would “only” apply to installations in Flood Hazard Areas.

The language “in locations prone to flooding” proposed for “(A)” is intentionally left undefined to provide the AHJ with discretion on interpretation and enforcement. The proponent envisions that “locations prone to flooding” would include areas that could be exposed to flooding from piping failures, operation of sprinkler systems, sump pumps, etc. On the other hand, the language in (B) Installations in Flood Hazard Areas is limited to installations in areas that are well defined and previously identified.

Reason for Rejection #1b Potential Conflict with Other Code Requirements

• Two of those occur in Article 540 Motion Picture Projection Rooms and one in Article 640 Electric Signs and Lighting where the term “flood” pertains to “flood” lights or “flood” lamps. Neither of those uses of the term flood pertains to the risk for flooding addressed by the proposed changes to Article 110.

• One instance occurs in Article 690 Solar Photovoltaic (PV) Systems which contains the term “flooded” but the use of that term pertains to “flooded” lead-acid batteries. It does not pertain to the risk of flooding addressed by the proposed changes to Article 110.

• There are other 11 instances where the terms “flood”, “flooded”, “flooding” or “floodplain” are used and, like the language proposed for Art 110, pertain to the risk of flooding or flood hazards. These instances are:
  1. Article 517 Health Care Facilities Art 517.35(C) Health Care Facilities – Essential Electrical Systems for Hospitals - Sources of Power
  2. Article 517 Health Care Facilities Art 517.44(C) Essential Electrical Systems for Nursing Homes and Limited Care Facilities - Sources of Power
  3. Article 626.22(B) Electrified Truck Parking Spaces
  4. Article 682.2(3) Natural and Artificially Made Bodies of Water
  5. Article 695.12(C) Fire Pumps
  6. Article 700 – Emergency Systems Art 700.10(C) Emergency Systems
  7. Article 700 – Emergency Systems Part III Art 700.12 General Requirements
  8. Article 701.12 – Legally Required Standby Systems Part III Sources of Power Art 701.12 General Requirements
  10. Article 708 – Critical Operations Power Systems (COPS) (3) Floodplain Protection
  11. Article 708 – Critical Operations Power Systems (COPS) and Art 708.11 Branch Circuit and Feeder Distribution Equipment

In all of these nine of the eleven instances, the language proposed for Article 110.10 does not conflict with existing requirements. In those cases, the proposed language contains more definitive and more enforceable methods to address flood risks than what exists in the present code. In other cases, requirements will differ. In those cases, the most stringent requirement will apply. The following contains excerpts from the 2014 NEC and lists the eleven instances where the terms “flood”, “flooded”, “flooding” or
"floodplain" are used. For each instance, the proponent has provided discussions on the effects of the proposed changes to Art 110. The terms flood, flooded, flooding or floodplain have been emphasized for clarity. These discussion were developed to assist the Committee in considering the proposed changes to Article 110.11

Article 517 Health Care Facilities

35 (C)  
"Location of Essential Electrical System Components. Careful consideration shall be given to the location of the spaces housing the components of the essential electrical system to minimize interruptions caused by natural forces common to the area (e.g., storms, floods, earthquakes, or hazards created by adjoining structures or activities). Consideration shall also be given to the possible interruption of normal electrical services resulting from similar causes as well as possible disruption of normal electrical service due to internal wiring and equipment failures. Consideration shall be given to the physical separation of the main feeders of the alternate source from the main feeders of the normal electrical source to prevent possible simultaneous interruption."

Proponent’s Response - This provision of the NEC Art 517 Sect 35(C) requires that floods be considered (carefully) when determining the location of Essential Systems in hospitals. NEC Art 517 Sect 44(C) contains nearly identical requirements for Nursing Homes and Limited Care Facilities. These articles do not state "how" floods should be considered when locating those systems but rather that floods need to be considered.

The proposed changes to Art 110 do not conflict with Art 517. Rather they contain more definitive, and more enforceable, methods to address flood risks. Those definitive and enforceable methods are consistent with those in the IBC, IRC and NFPA 5000.

Article 626.22(B) Electrified Truck Parking Spaces

"(B) Mounting Height. Post, pedestal, and raised concrete pad types of electrified truck parking space supply equipment shall be not less than 600 mm (2 ft) above ground or above the point identified as the prevailing highest water level mark or an equivalent benchmark based on seasonal or storm-driven flooding from the authority having jurisdiction."

Proponent’s Response - Article 626.22(B) requires post, pedestal, and raised concrete pad types of equipment supplying electrified truck parking spaces be elevated 2 feet above grade or to an elevation determined by the AHJ. The proposed changes to Art 110 require that, when located in a Flood Hazard Area, equipment supplying electrified truck parking spaces be elevated but the proposed changes to Art 110 also allow other methods of providing flood protection. Namely electrical equipment can be (1) designed and installed equipment to prevent flood waters from entering components and designed and installed to resist flood loads, or (2) by selecting equipment suitable for submerged use or (3) by protecting equipment by dry floodproofing.

Adopting the recommended changes to Art 110 will not create conflict but rather an instance where more stringent criteria would apply. The dry-floodproofing option, the option to use equipment suitable for submerged applications and the option of installing equipment that prevents floodwater entry allowed by Art 110 would not meet the requirements of Art 626 for post, pedestal, and raised concrete pad types of equipment that supply electrified truck parking spaces so the more stringent criteria of Art 626 would apply.

Article 682.2 (3) Natural and Artificially Made Bodies of Water

"Electrical Datum Plane". The electrical datum plane as used in this article is defined as follows:

(1) In land areas subject to tidal fluctuation, the electrical datum plane is a horizontal plane 600 mm (2 ft) above the highest tide level for the area occurring under normal circumstances, that is, highest high tide.

(2) In land areas not subject to tidal fluctuation, the electrical datum plane is a horizontal plane 600 mm (2 ft) above the highest water level for the area occurring under normal circumstances.

(3) In land areas subject to flooding, the electrical datum plane based on (1) or (2) above is a horizontal plane 600 mm (2 ft) above the point identified as the prevailing high water mark or an equivalent benchmark based on seasonal or storm-driven flooding from the authority having jurisdiction."

"682.10 Electrical Equipment and Transformers. Electrical equipment and transformers, including their enclosures, shall be specifically approved for the intended location. No portion of an enclosure for electrical equipment not identified for operation while submerged shall be located below the electrical datum plane."

"682.11 Location of Service Equipment. On land, the service equipment for floating structures and submersible electrical equipment shall be located no closer than 1.5 m (5 ft) horizontally from the shoreline and live parts shall be elevated a minimum of 300 mm (12 in.) above the electrical datum plane. Service equipment shall disconnect when the water level reaches the height of the established electrical datum plane."

Proponent’s Response –Art 682 requires electrical equipment, transformers and service equipment be elevated 2 feet above the Electrical Datum Plane - an elevation defined within that article. The elevation specified in Article 110.11 – the Based Flood Elevation - may be different from the Electrical Datum Plane so, in Flood Hazard Areas, a conflict could arise. However, the proposed language for Art 110 excludes wiring installed under Art 626 so no conflict will arise.
Article 695.12(C) – Fire Pumps

“(C) Storage Batteries. Storage batteries for fire pump engine drives shall be supported above the floor, secured against displacement, and located where they are not subject to physical damage, flooding with water, excessive temperature, or excessive vibration”.

Proponent’s Response - The elevation and dry floodproofing criteria proposed for Art 110 will protect storage batteries from being flooded with water – at least during a design flood. The proposed changes to Art 110 would allow storage batteries to be placed below the flood elevation and thus exposed to being flooded with water but only if they were sealed to prevent water entry or designed for submerged use. In those cases, Art 110 could expose storage batteries to flooding with water. In those instances, Art 695 would be more stringent and its criteria would supersede that of Art 110.

Article 700.10(C) – Emergency Systems Part II Circuit Wiring - Emergency System.

“(C) Wiring Design and Location. Emergency wiring circuits shall be designed and located so as to minimize the hazards that might cause failure due to flooding, fire, icing, vandalism, and other adverse conditions.”

Proponent’s Response – Article 700 requires wiring in emergency systems be designed to minimize flood hazards. Adopting the proposed changes to Article 110 will not create a conflict with Art 700. Rather, it will provide the protection required by Art 700 using substantive, quantifiable and enforceable criteria.

Article Emergency Systems Part III. Sources of Power 700.12 – General Requirements

“700.12 General Requirements. Current supply shall be such that, in the event of failure of the normal supply to, or within, the building or group of buildings concerned, emergency lighting, emergency power, or both shall be available within the time required for the application but not to exceed 10 seconds. The supply system for emergency purposes, in addition to the normal services to the building and meeting the general requirements of this section, shall be one or more of the types of systems described in 700.12(A) through (E). Unit equipment in accordance with 700.12(F) shall satisfy the applicable requirements of this article.

In selecting an emergency source of power, consideration shall be given to the occupancy and the type of service to be rendered, whether of minimum duration, as for evacuation of a theater, or longer duration, as for supplying emergency power and lighting due to an indefinite period of current failure from trouble either inside or outside the building.

Equipment shall be designed and located so as to minimize the hazards that might cause complete failure due to flooding, fires, icing, and vandalism….”

Proponent’s Response – Art 700.12 requires that sources of emergency power sources be designed to minimize the risk of a complete failure from numerous hazards one hazard being flooding. Adopting the proposed changes to Article 110 will not conflict with Art 700.12. Rather it will protect emergency sources from flooding using language that is more substantive, quantifiable and enforceable than the existing language.

Article Legally Required Standby Systems Part II Circuit Wiring 701.12 – Sources of Power

“701.12 General Requirements. Current supply shall be such that, in the event of failure of the normal supply to, or within, the building or group of buildings concerned, legally required standby power will be available within the time required for the application but not to exceed 60 seconds. The supply system for legally required standby purposes, in addition to the normal services to the building, shall be permitted to comprise one or more of the types of systems described in 701.12(A) through (F). Unit equipment in accordance with 701.12(G) shall satisfy the applicable requirements of this article.

In selecting a legally required standby source of power, consideration shall be given to the type of service to be rendered, whether of short-time duration or long duration.

Consideration shall be given to the location or design, or both, of all equipment to minimize the hazards that might cause complete failure due to floods, fires, icing, and vandalism.”

Proponent’s Response – Art 701.12 requires that flooding (and other hazards) be considered when locating sources for legally required standby systems. Adopting the proposed changes to Article 110 will not conflict with Art 701.12. Rather it will protect sources for legally required standby systems from flooding using language that is more substantive, quantifiable and enforceable than the existing language.

Article 708 Critical Operations Power Systems (COPS)

Art 708.10(C)(3) Circuit Wiring and Equipment “(3) Floodplain Protection. Where COPS feeders are installed below the level of the 100-year floodplain, the insulated circuit conductors shall be listed for use in a wet location and be installed in a wiring method that is permitted for use in wet locations.
Proponent’s Response - Article 708 allows feeders to be installed below the 100-year floodplain (i.e. the BFE) but only requires the feeds to be suitable for wet locations. In installations located in Flood Hazard Areas, Article 110 allows feeders to be installed below the BFE but requires them to be either (1) designed and installed to prevent flood waters from entering or accumulating within them and be designed to resist flood forces, or (2) suitable for submerged applications and be designed to resist flood forces or (3) protected by dry floodproofing that provides protection to one foot above the BFE. For installation in flood hazard areas, the proposed changes to Article 110 are more stringent than those of Art 708.

Article 708.11 – Circuit Wiring and Equipment

“(A) Branch Circuit Distribution Equipment. COPS branch circuit distribution equipment shall be located within the same DCOA as the branch circuits it supplies.

(B) Feeder Distribution Equipment. Equipment for COPS feeder circuits (including transfer equipment, transformers, and panelboards) shall comply with (1) and (2).

(1) Be located in spaces with a 2-hour fire resistance rating

(2) Be located above the 100-year floodplain.”

Proponent’s Response - Article 708 requires equipment for COPS feeder circuits be elevated above the 100-year floodplain (the BFE). The elevation criteria proposed for Article 110 require electrical equipment to be elevated a minimum of one foot above the

Committee Action: Accepted
Resolution: SR-3-NFPA 70-2015
Statement: The 2015 edition has been reaffirmed by ANSI.
Public Comment No. 1551-NFPA 70-2015 [Section No. 110.14 [Excluding any Sub-Sections]]

Because of different characteristics of dissimilar metals, devices such as pressure terminal or pressure splicing connectors and soldering lugs shall be identified for the material of the conductor and shall be properly installed and used. Conductors of dissimilar metals shall not be intermixed in a terminal or splicing connector where physical contact occurs between dissimilar conductors (such as copper and aluminum, copper and copper-clad aluminum, or aluminum and copper-clad aluminum), unless the device is identified for the purpose and conditions of use. Materials such as solder, fluxes, inhibitors, and compounds, where employed, shall be suitable for the use and shall be of a type that will not adversely affect the conductors, installation, or equipment.

(Exception) Where the connection is protected against any galvanic corrosion by incasing connection from an electrolyte.

Connectors and terminals for conductors more finely stranded than Class B and Class C stranding as shown in Chapter 9, Table 10, shall be identified for the specific conductor class or classes.

Statement of Problem and Substantiation for Public Comment

As a Master electrician for over 30 years, I have witnessed and dealt with the effects of poor grounding. A large part of this stems from the connection point of the GEC to the Grounding Electrode. Section 110.14 of the NEC Handbook describes this issue, yet does not address it completely. Dissimilar metal connections are used frequently in the electrical industry. Copper to galvanized ground rods, copper to steel rebar, aluminum to copper ground rods.

Even with "listed" connectors the industry does not address the facts that to dissimilar metals create a battery of such to sacrifices the anode to the cathode.

(see attached article)

This is creating a loose and unstable connection point that can lead to a great hazard to both life and property.

The industry also has been led to believe by the creators of exothermic welding that their connections are 100% free from galvanic corrosion. This is proving not to be the case, thus companies such as Century Link, civil engineering firms in St. Louis, Mo and US Dept. of the Interior – Mining and others are requiring a sealant over their exothermic welding connections which are then either buried deep beneath the soil or in concrete. Many companies such as Enbridge and Monsanto require annual inspections of these connections to check that the connection is still sound.

Since the grounding system is dormant a large part of it’s life we as electricians tend to over look it till it’s too late. Once the grounding system is needed do to a fault or lightning strike occurs we want to have the peace of mind knowing our grounding system is working properly.

Studies show that nearly 86% of all electrical problems stem from poor grounding. While proper installation of grounding equipment is closely regulated, post installation inspection has been largely overlooked. Recent growth spurts in the electrical industry have been bringing attention to these issues, with safety being the utmost concern.

All electrical systems rely on a good ground connection to ensure safe and reliable operation. Making sure there is minimal resistance at the grounding point ensures that any potential hazards are avoided.

The safest and simplest way to achieve these goals are by encapsulating the connection point. As read in the attached paper "Galvanic Corrosion in the Electrical Industry" put together by John Langholtz EE/PE graduate of South Dakota State University.

Public Comment No. 976-NFPA 70-2015 [Section No. 110.14(B)]

(B) Splices.
Conductors shall be spliced or joined with splicing devices identified for the use or by brazing, welding, or soldering with a fusible metal or alloy. Soldered splices shall first be spliced or joined so as to be mechanically and electrically secure without solder and then be soldered. All splices and joints and the free ends of conductors shall be covered with an insulation equivalent to that of the conductors or with an identified insulating device.

Wire connectors or splicing means installed on conductors for direct burial shall be listed and labeled for such use.

Statement of Problem and Substantiation for Public Comment

CMP 1 within the committee statement stated "This section currently aligns with common labeling requirements in product safety standards," the product safety standards do not include requirements for certification (listing) labels. The statement also stated "Labeling of listed equipment is not possible in all cases or conditions such as if products are too small to be labeled or for some severe environmental conditions. Manufacturers require the flexibility afforded for listed products relative to when labels should be applied and when the information on the smallest package is sufficient, and practical." This statement seems to reinforce the need for an informational note to the definition of labeled as submitted under PI 1072.

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term "and labeled" was added after "listed" during the First Revision Stage, the words "and labeled" after "listed" be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms "listed" and "labeled," most importantly, to clarify and establish a distinction between the terms "listed" and "labeled" which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of "listed and labeled." As such, UL is submitting comments to request that the words "and labeled" be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer's attestation that the product is in compliance with the appropriate standard. NRTL's conduct factory surveillance of products, surveillance is one method to validate the manufacturer's attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the "Listing" is not impacted, as the "listing" is created at the completion of the "original" certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a "listing" has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL's do not consider a product as being listed unless it is also labeled. The UL White Book states that "Only those products bearing the appropriate UL Mark and the company's name, trade name, trademark or other authorized identification should be considered as being covered by UL's Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards." Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL's have similar requirements.

Committee Statement

Committee Action: Rejected but held
Resolution: The inconsistent actions on Public inputs to globally change the term “listed or labeled” to “listed and labeled” resulted in multiple inconsistencies through the NEC and created conflicts with other Codes and Standards that use the term. CMP-1 understands that the NEC Correlating Committee took action to develop a first revision that restores the NEC rules using the term listed or labeled to how those rules appeared in the 2014 edition. CMP-1 also understands that the NEC Correlating Committee has formed a Task Group to globally review the use of the term “listed or labeled” throughout the NEC and determine a simplified solution that addresses the terms listed, labeled, and their associated informational notes. The Task Group is to address the concerns and input from multiple qualified electrical testing laboratories and work toward a simple solution that resides within Article 100 and perhaps Article 110. The work of that task group is just getting started and may include proposed revisions to these existing definitions and associated informational notes. CMP-1 recognizes it is premature to incorporate the proposed revisions and informational note at this time.
Public Comment No. 1078-NFPA 70-2015 [Section No. 110.14(C)(1)]

(1) Equipment Provisions.
The determination of termination provisions of equipment shall be based on 110.14(C)(1)(a) or (C)(1)(b). Unless the equipment is listed and marked otherwise, conductor ampacities used in determining equipment termination provisions shall be based on Table 310.15(B)(16) as appropriately modified by 310.15(B)(7).

(a) Termination provisions of equipment for circuits rated 100 amperes or less, or marked for 14 AWG through 1 AWG conductors, shall be used only for one of the following:

(2) Conductors rated 60°C (140°F).

(3) Conductors with higher temperature ratings, provided the ampacity of such conductors is determined based on the 60°C (140°F) ampacity of the conductor size used.

(4) Conductors with higher temperature ratings if the equipment is listed and identified for use with such conductors.

(5) For motors marked with design letters B, C, or D, conductors having an insulation rating of 75°C (167°F) or higher shall be permitted to be used, provided the ampacity of such conductors does not exceed the 75°C (167°F) ampacity.

(f) Termination provisions of equipment for circuits rated over 100 amperes, or marked for conductors larger than 1 AWG, shall be used only for one of the following:

(7) Conductors rated 75°C (167°F)

(8) Conductors with higher temperature ratings, provided the ampacity of such conductors does not exceed the 75°C (167°F) ampacity of the conductor size used, or up to their ampacity if the equipment is listed and identified for use with such conductors.

Statement of Problem and Substantiation for Public Comment

Justification: The wording deleted by this proposed change was added in the 2002 code (proposed by the Square D Company) as a means to clarify or simplify equipment termination calculations. It was argued that the change and I quote “This proposal does not have any new impact on the equipment or wiring methods”.

In fact this code change has been interpreted by some, to have a significant impact by excluding the use of Cable Bus and Cable tray in most applications, as these wiring methods are not dictated or based on table 310.16. Cable tray and Cable Bus systems have been valued wiring methods, connecting to equipment, without issue for nearly 50 years.

If equipment is designed based on cable ampacities listed in table 310.16 this specific requirement needs to be stated in the manufacturer’s equipment specifications and provided on the equipment terminations. This design criteria should not be imposed with a broad brush for all “equipment” as currently written in this section of the code.

Resolution: Removing the reference to 310.15(B)(7) is not technically substantiated.
Public Comment No. 87-NFPA 70-2015 [ Section No. 110.14(C)(1) ]

(1) Equipment Provisions.

The determination of termination provisions of equipment shall be based on 110.14(C)(1)(a) or (C)(1)(b). Unless the equipment is listed and marked otherwise, conductor ampacities used in determining equipment termination provisions shall be based on from either Table 310.15(B)(16) as appropriately modified by 310.15(B)(7) or Table 310.15(B)(17) as appropriate.

(a) Termination provisions of equipment for circuits rated 100 amperes or less, or marked for 14 AWG through 1 AWG conductors, shall be used only for one of the following:

(2) Conductors rated 60°C (140°F).

(3) Conductors with higher temperature ratings, provided the ampacity of such conductors is determined based on the 60°C (140°F) ampacity of the conductor size used.

(4) Conductors with higher temperature ratings if the equipment is listed and identified for use with such conductors.

(5) For motors marked with design letters B, C, or D, conductors having an insulation rating of 75°C (167°F) or higher shall be permitted to be used, provided the ampacity of such conductors does not exceed the 75°C (167°F) ampacity.

(f) Termination provisions of equipment for circuits rated over 100 amperes, or marked for conductors larger than 1 AWG, shall be used only for one of the following:

(7) Conductors rated 75°C (167°F)

(8) Conductors with higher temperature ratings, provided the ampacity of such conductors does not exceed the 75°C (167°F) ampacity of the conductor size used, or up to their ampacity if the equipment is listed and identified for use with such conductors.

Statement of Problem and Substantiation for Public Comment

The current wording is limiting the methods by which equipment may be connected by implying all equipment connections are limited to the ampacities stated within table 310.15(B)(16). Where as this rule may apply to some equipment applying it to all equipment is being overly restrictive, by inserting this additional table it will not limit the use of other traditional wiring methods such as cable tray and cable bus.

This simply allows the use of table 310.15(B)(17) for wiring methods without special marking or labeling as was the standard prior to the insertion of only table 310.15(B)(16) in the 2002 NEC. Either table when used in conjunction with section 110.14 C should have no new impact on wiring or equipment. Section 110.14 C clearly indicates that "The temperature rating associated with the ampacity of a conductor shall be selected and coordinated so as not to exceed the lowest temperature rating of any connected termination, conductor, or device."

Submittal Date: Mon Jun 29 12:12:12 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: Adding the reference to 310.15(B)(17) is not technically substantiated.
Public Comment No. 1458-NFPA 70-2015 [Section No. 110.14(D)]

(D) Installation.

Where a tightening torque is indicated as a numeric value on equipment or in installation instructions provided by the manufacturer, a calibrated torque tool shall be used to achieve the indicated torque value, unless the equipment manufacturer has provided installation instructions for an alternative method of achieving the required torque. Documentation shall be provided, by the installing entity, to the AHJ certifying that the required tightening torque values for such equipment have been met, prior to energizing the equipment.

Statement of Problem and Substantiation for Public Comment

Fr 40 clearly identifies the fact that following the manufacturer's guidelines for tightening torque is a safety issue. As such, the inspection community should have a method to provide assurance that the installer followed the guidelines needed to ensure the installation is safe. Simply looking at the connections is not an option.

Submittal Date: Fri Sep 25 12:27:01 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The additional requirement proposed in PC 1458 is overly restrictive and not practical. Documenting terminations in equipment have been tightened to manufacturer’s requirements in accordance with the marked values on equipment is an increased awareness of what was already required under the installation and use requirements in 110.3(B). There was no substantiation provided to indicate there is a problem for enforcement if documented torque values are not provided.
110.16 Arc-Flash Hazard Warning.

(A) General.

Electrical equipment, such as switchboards, switchgear, panelboards, industrial control panels, meter socket enclosures, and motor control centers, that is in other than dwelling units, and is likely to require examination, adjustment, servicing, or maintenance while energized, shall be field or factory marked to warn qualified persons of potential electric arc flash hazards. The marking shall meet the requirements in 110.21(B) and shall be located so as to be clearly visible to qualified persons before examination, adjustment, servicing, or maintenance of the equipment.

(B) Service Equipment.

In addition to the requirements in (A), service equipment shall contain the following information:

(1) Nominal system voltage
(2) Arc flash boundary
(3) At least one of the following:
   (c) Available incident energy and the corresponding working distance
   (c) Minimum arc rating of clothing
   (c) Site-specific level of PPE

Informational Note No. 1: NFPA 70E-2012, Standard for Electrical Safety in the Workplace, provides guidance, such as determining severity of potential exposure, planning safe work practices, arc flash labeling, and selecting personal protective equipment.

Informational Note No. 2: ANSI Z535.4-1998, Product Safety Signs and Labels, provides guidelines for the design of safety signs and labels for application to products.

Statement of Problem and Substantiation for Public Comment

The Correlation Committee directs the panel to review the action taken on FR 55 and clarify the correct edition dates. Informational Note No. 1 references the 2012 edition of NFPA 70E; however, the Committee Statement indicates the revisions were made based on the 2015 edition. Informational Note No. 2 references the 1998 edition of ANSI Z535.4 but FR 43 references the 2011 edition.

Statement

Committee Statement

Submitted by: CC on NEC-AAC
Organization: NFPA
Street Address:
City:
State:
Zip:
Submittal Date: Mon Sep 28 14:45:53 EDT 2015

Committee Action: Rejected but see related SR
Resolution: SR-11-NFPA 70-2015
Statement: This Second Revision makes installation-related revisions and clarifications to FR55 as suggested in First Revision Public Input, First Revisions and ballot comments.

The addition of available fault current and clearing time has been added. This, like all revisions in this SR, does not represent new material. FR55 contained a requirement to label incident-energy which is based upon current and time.

Changing from incident energy to available fault current and clearing time simplifies the installation for the installer. In order to get an incident energy value both the available fault current and clearing time are determined and then a calculation is performed. It is simply the requirement to calculate incident energy with known values of current and time that is removed, thereby removing from the installer the requirement to calculate.
The label is permitted to be either field or factory applied.

Clarifying language has also been added to recognize that (B) only applies to “other than dwelling units.”

Language was added for the label to contain the date the label was applied.

An equipment rating was established to limit the installations in which this requirement would apply. FR55 would have applied at any equipment rating, including those below 1,200 amperes. The addition of the 1200-amp threshold is not new material as it does not increase the application of this requirement, it significantly reduces the number of installations in which it would apply.

Informational Note No. 3 was added to provide guidance on acceptable industry practices for developing arc-flash labels, incident energy levels, arc-flash boundaries, and minimum required levels of personal protective equipment and so forth.

Dates were edited to reflect current editions.
Public Comment No. 1058-NFPA 70-2015 [Section No. 110.16(B)]

(B) Service Equipment.
In addition to the requirements in (A), service equipment shall contain the following field or factory marked information:

1. Nominal system voltage
2. Arc flash boundary
3. At least one of the following:
   a. Available incident energy and the corresponding working distance
   b. Minimum arc rating of clothing
   c. Site-specific level of PPE

Informational Note No. 1: NFPA 70E-2012, Standard for Electrical Safety in the Workplace, provides guidance, such as determining severity of potential exposure, planning safe work practices, arc flash labeling, and selecting personal protective equipment.

Informational Note No. 2: ANSI Z535.4-1998, Product Safety Signs and Labels, provides guidelines for the design of safety signs and labels for application to products.

Statement of Problem and Substantiation for Public Comment

The marking requirement in 110.16(B) needs to be consistent with the marking requirement in 110.16(A). The current marking requirements for service equipment could be misunderstood to be only the manufacturer’s responsibility and should be clarified for appropriate enforcement.

Statement of Problem and Substantiation for Public Comment

Section 110.16 of the NEC is titled “Arc Flash Hazard Warning” so the information contained in this section should relate to a general warning for qualified persons. In previous NEC cycles, Code-Making-Panel 1 determined that the warning should remain general in nature and should not include information about how to protect against arc flash using Personal Protective Equipment (PPE). The NEC is an installation Code that provides information and requirements for electrical installations that essentially protect persons and property from hazards arising from use of electricity. The NEC should not include workplace safety requirements on how to protect against electric shock, arc-flash and arc-blast events that could occur when workers are performing energized work. The NEC does not have any of the information that is contained in NFPA 70E, including definitions for personal protective systems, for determining the arc flash energy of a completed electrical system.

If an electrical contractor’s work was only for the service and power to a disconnecting means for each piece of electrical equipment and was not involved in the actual electrical equipment connection, an arc fault calculation for the service and at each disconnect would not include motor contribution or overcurrent protection interruption values that ultimately may affect the amount of arcing energy available to determine the level of protection necessary for the service person. Would the electrical contractor who installed the electrical equipment be responsible for the arc energy calculation or the original electrical contractor? There also may be two clearing times, one at the service and one on the load side of service at the actual equipment on which the values on such a mark or label should be based, further complicating the proposed marking requirement. The values of energy provided on the arcing flash hazard label may not be accurate and may compromise worker safety. These proposed requirements appear to be beyond the NEC scope and should be provided only in NFPA 70E where all of the necessary information already resides. The owner of the facility is responsible for having the arc energy calculations done and for maintaining the accuracy and validity of these calculations and appropriate labels. The arc energy calculation and marking should not become an installation requirement in the NEC.

Resolution: See SR 11. CMP-1 reaffirms the need to retain the concepts of 110.16(B). Based on the comments received, the panel has revised the text to address the concerns noted in these PCs.
Public Comment No. 266-NFPA 70-2015 [Section No. 110.16(B)]

(B) Service Equipment.

In addition to the requirements in (A), service equipment, in other than dwelling units, shall contain the following information:

The calculations for the information required by (B)(2) and (B)(3) shall be based on the available fault current and clearing time for the utility supply where there are exposed service conductors in the service equipment. Where there are no exposed service conductors, the calculations shall be permitted to be based on the available fault current on the load side of the service overcurrent protective device.

1. Nominal system voltage
2. Arc flash boundary
3. At least one of the following:
   - Available incident energy and the corresponding working distance
   - Minimum arc rating of clothing
   - Site-specific level of PPE

Informational Note No. 1: NFPA 70E-2012, Standard for Electrical Safety in the Workplace, provides guidance, such as determining severity of potential exposure, planning safe work practices, arc flash labeling, and selecting personal protective equipment.

Informational Note No. 2: ANSI Z535.4-1998, Product Safety Signs and Labels, provides guidelines for the design of safety signs and labels for application to products.

Statement of Problem and Substantiation for Public Comment

It is not clear if (B) applies to dwelling unit service equipment. Since (A) clearly does not apply to dwelling unit service equipment, I don’t see why (B) would apply to dwelling unit service equipment.

The basis for the arc flash and incident energy calculations are also not clear in the first draft language. It appears to me that where there are exposed service conductors or bus, that the calculations should be based on the utility fault current and clearing time. If an fault would occur on the line side of the service OCPD, the utility OCPD must clear that fault and the posted information should reflect that. Where there are no exposed service conductors within the service equipment a fault on the line side of the service OCPD is much less likely and the calculations should be permitted to be based on the available fault current and clearing time on the load side of the service OCPD.

I understand that this will require the calculation for service equipment with multiple service disconnects to be based on the utility available fault current and clearing time and that is the intent of this comment.

Submittal Date: Sat Jul 18 12:47:50 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-11-NFPA 70-2015
Statement: This Second Revision makes installation-related revisions and clarifications to FR55 as suggested in First Revision Public Input, First Revisions and ballot comments.

The addition of available fault current and clearing time has been added. This, like all revisions in this SR, does not represent new material. FR55 contained a requirement to label incident-energy which is based upon current and time.
Changing from incident energy to available fault current and clearing time simplifies the installation for the installer. In order to get an incident energy value both the available fault current and clearing time are determined and then a calculation is performed. It is simply the requirement to calculate incident energy with known values of current and time that is removed, thereby removing from the installer the requirement to calculate.

The label is permitted to be either field or factory applied.

Clarifying language has also been added to recognize that (B) only applies to “other than dwelling units.”

Language was added for the label to contain the date the label was applied.

An equipment rating was established to limit the installations in which this requirement would apply. FR55 would have applied at any equipment rating, including those below 1,200 amperes. The addition of the 1200-amp threshold is not new material as it does not increase the application of this requirement, it significantly reduces the number of installations in which it would apply.

Informational Note No. 3 was added to provide guidance on acceptable industry practices for developing arc-flash labels, incident energy levels, arc-flash boundaries, and minimum required levels of personal protective equipment and so forth.

Dates were edited to reflect current editions.
Public Comment No. 327-NFPA 70-2015 [Section No. 110.16(B)]

(B) Service Equipment.

In addition to the requirements in (A), service equipment shall contain the following information:

1. Nominal system voltage
2. Arc flash boundary
3. At least one of the following:
   a. Available incident energy and the corresponding working distance
   b. Minimum arc rating of clothing
   c. Site-specific level of PPE

(d) The incident energy and corresponding working distance will be calculated on the load side of the breaker.

Informational Note No. 1: NFPA 70E-2012, Standard for Electrical Safety in the Workplace, provides guidance, such as determining severity of potential exposure, planning safe work practices, arc flash labeling, and selecting personal protective equipment.

Informational Note No. 2: ANSI Z535.4-1998, Product Safety Signs and Labels, provides guidelines for the design of safety signs and labels for application to products.

Statement of Problem and Substantiation for Public Comment

The incident energy must be at the panel and not upstream to understand the electrical hazard. The new language in NFPA 70 2014 for the label and the information on it is GREAT! We just need to improve it a bit. THANK YOU.

Statement of Problem and Substantiation for Public Comment

In my opinion, this is a maintenance issue and not a minimum design standard. This requirement is already covered in NFPA 70E. I understand the intent of this change, but I am concerned this change will create a hazardous situation. In an industrial setting, where all details are known, this is a good requirement. However, on smaller commercial projects this requirement could create a situation where inaccurate data is given to a maintenance electrician. Having this requirement in NFPA 70 will require electrical engineers to supply this information on the initial design of the project. I have two concerns with that approach.

1. On these small projects, changes are often made in the field that are not submitted back to the engineer for approval. A change as simple as adding an additional power pole to move the transformer bank closer to the service will make all original data inaccurate.

2. Some utility companies are now only giving worse case available fault current data based on an infinite bus. Worst case data is given to resolve the utility of any liability of future upgrades to the power system. While this seems to err on the safe side for available fault current, it will often provide lower than actual incident energy levels due to the predicted quick tripping of protection devices because of the falsely high fault current. Actual fault current levels will often require much more time to clear and thus increase the incident energy levels.

As a professional engineer, the only way I see to comply with this on most small commercial projects will be to list the incident energy level as above 40 cals/cm2 so the equipment cannot be worked on energized.

Informational Note No. 2: ANSI Z535.4-1998, Product Safety Signs and Labels, provides guidelines for the design of safety signs and labels for application to products.

Statement of Problem and Substantiation for Public Comment

IEC’s position is to delete FR 55.

IEC believes in safe work practices and environments for employees and understands the provisions provided in NFPA 70 E are a requirement for employers to follow. The added label requirements in FR 55 are already addressed in 70 E that places the responsibility on the owner including a date to warn workers when the label was created. The proposed revision is not consistent with 70 E and would create confusion for installers and inspectors and may compromise worker safety. IEC is concerned about the liability that may be associated with these added label requirements.

Committee Statement

Committee Action: Rejected but see related SR

Resolution: SR-11-NFPA 70-2015

Statement: This Second Revision makes installation-related revisions and clarifications to FR55 as suggested in First Revision Public Input, First Revisions and ballot comments.

The addition of available fault current and clearing time has been added. This, like all revisions in this SR, does not represent new material. FR55 contained a requirement to label incident-energy which is based upon current and time.

Changing from incident energy to available fault current and clearing time simplifies the installation for the installer. In order to get an incident energy value both the available fault current and clearing time are determined and then a calculation is performed. It is simply the requirement to calculate incident energy with known values of current and time that is removed, thereby removing from the installer the requirement to calculate.

The label is permitted to be either field or factory applied.

Clarifying language has also been added to recognize that (B) only applies to “other than dwelling units.”

Language was added for the label to contain the date the label was applied.

An equipment rating was established to limit the installations in which this requirement would apply. FR55 would have applied at any equipment rating, including those below 1,200 amperes. The addition of the 1200-amp threshold is not new material as it does not increase the application of this requirement, it significantly reduces the number of installations in which it would apply.

Informational Note No. 3 was added to provide guidance on acceptable industry practices for developing arc-flash labels, incident energy levels, arc-flash boundaries, and minimum required levels of personal protective equipment and so forth.

Dates were edited to reflect current editions.
(B) - Service Equipment.
In addition to the requirements in (A), service equipment shall contain the following information:

(1) Nominal system voltage
(2) Arc flash boundary
(3) At least one of the following:
   (4) Available incident energy and the corresponding working distance
   (5) Minimum arc rating of clothing
   (6) Site-specific level of PPE

Informational Note No. 1: NFPA 70E-2012, Standard for Electrical Safety in the Workplace, provides guidance, such as determining severity of potential exposure, planning safe work practices, arc flash labeling, and selecting personal protective equipment.

Informational Note No. 2: ANSI Z535.4-1998, Product Safety Signs and Labels, provides guidelines for the design of safety signs and labels for application to products.

Statement of Problem and Substantiation for Public Comment
NECA stands in opposition to First Revision 55 that expands the label requirements in 110.16. Public Inputs (551, 493, 4789, 4626, 3973, and 1491) should have been resolved. NECA is mindful of the obligations to provide safe work environments for employees and understands requirements contained within both NFPA 70 National Electrical Code and NFPA 70E Standard for Electrical Safety in the Workplace. Section 110.16 of the NEC is titled “Arc Flash Hazard Warning.” The information contained in this section should continue to relate to a generic warning for qualified persons. As resolved by NEC CMP-1 in previous NEC development cycles, the warning should remain general in nature and should not include information about “how to” protect using PPE, because this section is not about “how to protect.” The NEC is an installation Code that provides information and requirements for electrical installations that essentially protect persons and property from hazards arising from “use of electricity.” It should not include workplace safety requirements related to how to protect against electric shock, arc-flash and arc-blast events that could occur when workers are performing energized work, justified or not justified. The label requirements proposed in FD 55 are currently addressed in NFPA 70E, as they should be. The proposed NEC revision would be inconsistent with the requirements in 70E and would introduce confusion for installers and inspectors, and would not be practical or enforceable. Many inspectors would not fully understand the information on such labels and whether the information was accurate, and be expected to approve it. It also creates problems for manufacturers that current provide generic arc-flash hazard-warning labels at the factory, which is current provision in this section. The responsibility for this type of marking detail rests with owners, as indicated in NFPA 70E. With no date and time included in the proposed marking, there are serious concerns about the validity and accuracy of such information after the service equipment is initially marked. Another problem is that there are two clearing times (lines side of service OCPD and load side of service OCPD) upon which the values on such a mark or label should be based, further complicating the proposed marking requirement. NECA is also concerned that a false sense of security that might be created, and that the values of energy provided on such marks would not be accurate and compromise worker and owner safety. NECA believes these proposed requirements are inappropriate in the NEC and should be provided only in NFPA 70E. It is important to realize that according to 70E, the owners have the responsibility to maintain the label information accuracy and validity, which presents a whole variety of problems and concerns, given how much attention owners typically do not provide to equipment maintenance issues, which would include maintaining the accurate information on these labels. NECA continues to emphasize that compliance with NFPA 70E is a requirement, not an option.

Statement of Problem and Substantiation for Public Comment

This proposed revision includes a requirement that the label contain the date of application as correctly pointed out by multiple CMP-1 members in their affirmative comments. Additionally text is added to ensure that the label is permanent and suitable for the environment in which it is applied. Further clarity is provided by adding prescriptive text that the label is based upon the load side of the service overcurrent device.

There has been much discussion as to whether such a requirement is an installation requirement or a work practices issue. This issue was discussed by the NEC Correlating Committee at length after the First Draft meeting and the overwhelming decision was that this requirement belongs in the NEC and not NFPA 70E.

NFPA 70E is not adopted by OSHA, states, cities or municipalities. NFPA 70E is a standard, not a code. Standards are designed to be adopted into other codes or regulations. In the Foreword to NFPA 70E it is clearly stated that 70E is designed to assist OSHA. It is imperative to understand that OSHA does not require this type of label. Only where the equipment owner is proactive and decides to label does this occur. If labeling were an OSHA requirement there would be no need for FR 55. Employers must follow federal/state requirements and legally adopted codes for electrical installations and "none" require labeling. This revision will now require that at a minimum, the service equipment will be labeled.

NFPA 70E is not a requirement. OSHA is the "shall" and NFPA 70E shows the employer "how." This new requirement will be mandatory.

The NEC Correlating Committee reviewed the history of this issue in the NEC and overwhelmingly decided that this requirement is within the purview of the NEC. FR 55 is not new to the NEC process. If the NEC Correlating Committee had determined that this requirement was outside of the scope of the NEC, we would have some serious deleting to do. There are countless installation requirements that exist solely for the safety of persons that will examine, adjust, service, or maintain electrical equipment while energized. These requirements include but are not limited to: current arc flash warning labels, workspace clearances, arc energy reduction requirements, disconnects within sight of equipment and equipment labeling requirements. None of these requirements are necessary for safe installation and operation but all are critically important for the safety of persons that will examine, adjust, service, or maintain electrical equipment while energized.

A precedent is set, this issue has repeatedly been in the NEC revision process without any comment from the NEC Correlating Committee including this revision cycle. See proposal 1-235 in the 2001 ROP. This proposal added a similar requirement to that seen in FR 55. The NEC Correlating Committee agreed that this issue was appropriate and within the scope of the NEC. In fact the Correlating Committee added a note to change the word "residential" to "dwelling!" This is one of many such examples.

Submittal Date: Tue Sep 22 14:49:27 EDT 2015
Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-11-NFPA 70-2015
Statement: This Second Revision makes installation-related revisions and clarifications to FR55 as suggested in First Revision Public Input, First Revisions and ballot comments.

The addition of available fault current and clearing time has been added. This, like all revisions in this SR, does not represent new material. FR55 contained a requirement to label incident-energy which is based upon current and time.

Changing from incident energy to available fault current and clearing time simplifies the installation for the installer. In order to get an incident energy value both the available fault current and clearing time are determined and then a calculation is performed. It is simply the requirement to calculate incident energy with known values of current and time that is removed, thereby removing from the installer the requirement to calculate.

The label is permitted to be either field or factory applied.

Clarifying language has also been added to recognize that (B) only applies to “other than dwelling units.”

Language was added for the label to contain the date the label was applied.

An equipment rating was established to limit the installations in which this requirement would apply. FR55 would have applied at any equipment rating, including those below 1,200 amperes. The addition of the 1200-amp threshold is not new material as it does not increase the application of this requirement, it significantly reduces the number of installations in which it would apply.

Informational Note No. 3 was added to provide guidance on acceptable industry practices for developing arc-flash labels, incident energy levels, arc-flash boundaries, and minimum required levels of personal protective equipment and so forth.

Dates were edited to reflect current editions.
Public Comment No. 1540-NFPA 70-2015 [Section No. 110.21]

110.21 Marking.
   (A) Equipment Markings.
   (1) The manufacturer's name, trademark, or other descriptive marking by which the organization responsible for the product can be identified shall be placed on all electrical equipment. Other markings that indicate voltage, current, wattage, or other ratings shall be provided as specified elsewhere in this Code. The marking or label shall be of sufficient durability to withstand the environment involved.
   (2) Reconditioned equipment shall be marked with the name, trademark, or other descriptive marking by which the organization responsible for reconditioning the electrical equipment can be identified, along with the date of the reconditioning. Informational Note: Industry standards are available for application of reconditioned and refurbished equipment.

B) Field-Applied Hazard Markings.
   Where caution, warning, or danger signs or labels are required by this Code, the labels shall meet the following requirements:
   (1) The marking shall warn of the hazards using effective words, colors, symbols, or any combination thereof. Informational Note: ANSI Z535.4-2011, Product Safety Signs and Labels, provides guidelines for suitable font sizes, words, colors, symbols, and location requirements for labels.
   (2) The label shall be permanently affixed to the equipment or wiring method and shall not be hand written. Exception to (2): Portions of labels or markings that are variable, or that could be subject to changes, shall be permitted to be hand written and shall be legible.
   (3) The label shall be of sufficient durability to withstand the environment involved. Informational Note: ANSI Z535.4-2011, Product Safety Signs and Labels, provides guidelines for the design and durability of safety signs and labels for application to electrical equipment.

Statement of Problem and Substantiation for Public Comment

The addition of marking requirements for refurbished or remanufactured equipment should not have been accepted. It appears the primary intent of this change is to provide traceability of refurbished or remanufactured equipment resold by 3rd parties and used to replace existing equipment. Providing company name and trademark labels on equipment that is regularly maintained and/or refurbished by the owner/operator as part of a regular equipment maintenance program does not enhance the traceability of the work, nor does it necessarily improve the safety of the installation, which is the purpose of the NEC.

Submittal Date: Fri Sep 25 13:56:48 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: See SR 9. CMP-1 reaffirms its position on FR 42 that incorporation of language the more specifically clarifies that the term equipment refers to all equipment including new or other types.
The manufacturer’s name, trademark, or other descriptive marking by which the organization responsible for the product can be identified shall be placed on all electrical equipment. Other markings that indicate voltage, current, wattage, or other ratings shall be provided as specified elsewhere in this Code. The marking or label shall be of sufficient durability to withstand the environment involved.

Reconditioned equipment shall be marked with the name, trademark, or other descriptive marking by which the organization responsible for reconditioning the electrical equipment can be identified, along with the date of the reconditioning. Informational Note: Industry standards are available for application of reconditioned and refurbished equipment. Exception: In industrial occupancies, where conditions of maintenance and supervision ensure that only qualified persons service the equipment, the markings indicated in 110.21(A)(2) are not required.

Field-Applied Hazard Markings

Where caution, warning, or danger signs or labels are required by this Code, the labels shall meet the following requirements:

1. The marking shall warn of the hazards using effective words, colors, symbols, or any combination thereof. Informational Note: ANSI Z535.4-2011, Product Safety Signs and Labels, provides guidelines for suitable font sizes, words, colors, symbols, and location requirements for labels.

2. The label shall be permanently affixed to the equipment or wiring method and shall not be hand written. Exception to (2): Portions of labels or markings that are variable, or that could be subject to changes, shall be permitted to be hand written and shall be legible.

3. The label shall be of sufficient durability to withstand the environment involved. Informational Note: ANSI Z535.4-2011, Product Safety Signs and Labels, provides guidelines for the design and durability of safety signs and labels for application to electrical equipment.

Statement of Problem and Substantiation for Public Comment

Note: the only change proposed is a new exception to 110.21(A)(2). It appears the primary intent of this change is to provide traceability of refurbished or remanufactured equipment resold by 3rd parties and used to replace existing equipment. Industrial facilities regularly maintain and refurbish equipment as part of a regular maintenance cycle for safety and reliability. Providing company name and trademark labels on equipment that is regularly maintained and/or refurbished by the owner/operator as part of a regular equipment maintenance program does not enhance the traceability of the work or improve the safety of the installation.

Committee Statement

Committee Rejected but see related SR
SR-9 incorporates suggestions from PCs 582, 707 and 1550.

This provides additional guidance for reconditioned equipment. When a listed product is reconditioned (such as being rebuilt, refurbished or remanufactured) after it leaves a factory where the listing mark was applied, the organization responsible for the testing and inspection (as detailed in NEC Section 90.7) does not know if the product continues to meet the applicable certification requirements unless the reconditioning has been specifically evaluated by an organization properly equipped and qualified for making such determinations. Therefore, the AHJ should not rely solely on the equipment's original listing mark as the basis of approval of the "reconditioned equipment."

Industrial facilities may regularly maintain and refurbish equipment as part of a regular maintenance cycle for safety and reliability. Providing company name and trademark labels on equipment that is regularly maintained and/or refurbished by the owner/operator as part of a regular equipment maintenance program does not enhance the traceability of the work or improve the safety of the installation.

The language is added in the informational note to make it clear that normal service work such as replacing a fuse, circuit breaker or other routine work is generally not considered refurbishing or reconditioning of equipment.
Public Comment No. 582-NFPA 70-2015 [Section No. 110.21(A)(2)]

(2) Reconditioned equipment shall be marked with the name, trademark, or other descriptive marking by which the organization responsible for reconditioning the electrical equipment can be identified, along with the date of the reconditioning. Reconditioned equipment shall be identified as “reconditioned” and shall be acceptable only if approved. Approval of the reconditioned equipment shall not be based solely on the equipment’s original listing.

Informational Note: Industry standards are available for application of reconditioned and refurbished equipment.

Products which are listed when originally manufactured may be labeled with the label, symbol, or other identifying mark of the organization that performed the examination of the equipment as it was originally manufactured. One method for approval of reconditioned equipment is for the reconditioned equipment to be examined and relabeled by an organization that conforms to the requirements of Section 90.7.

Statement of Problem and Substantiation for Public Comment

This public comment provides additional guidance needed to evaluate reconditioned equipment. Text is proposed for the new 110.21(A)(2) that would follow the enforcement requirements in 110.2.

The Information Note is revised to remove the reference to unspecified Standards, and to include an explanation that the AHJ can use the same approval process that is customary for “listed and labeled” equipment.

As “reconditioned equipment” is introduced into this Code Section, it is important to note that the listing mark is a manufacturer’s declaration that a product was manufactured in accordance with the applicable listing requirements, and was in compliance with those requirements when it was shipped from the factory. When a listed product is reconditioned (or rebuilt, refurbished or remanufactured) after it leaves a factory where the listing mark was applied, the organization responsible for the testing and inspection (as detailed in NEC Section 90.7) does not know if the product continues to meet the applicable certification requirements unless the reconditioning has been specifically evaluated by an organization properly equipped and qualified for making such determinations. Therefore, the AHJ should not rely solely on the equipment’s original listing mark as the bases of approval of the “reconditioned equipment.”

AHJs are responsible for assessing the acceptability of any reconditioned equipment and may choose to rely on a “Rebuilt,” “Refurbished” or “Remanufactured” listing promulgated by organizations properly equipped and qualified, as described in NEC Section 90.7, as a basis for approval.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-9-NFPA 70-2015
Statement: SR 9 incorporates suggestions from PCs 582, 707 and 1550.

This provides additional guidance for reconditioned equipment. When a listed product is reconditioned (such as being rebuilt, refurbished or remanufactured) after it leaves a factory where the listing mark was applied, the organization responsible for the testing and inspection (as detailed in NEC Section 90.7) does not know if the product continues to meet the applicable certification requirements unless the reconditioning has been specifically evaluated by an organization properly equipped and qualified for making such determinations. Therefore, the AHJ should not rely solely on the equipment’s original listing mark as the basis of approval of the “reconditioned equipment.”
Industrial facilities may regularly maintain and refurbish equipment as part of a regular maintenance cycle for safety and reliability. Providing company name and trademark labels on equipment that is regularly maintained and/or refurbished by the owner/operator as part of a regular equipment maintenance program does not enhance the traceability of the work or improve the safety of the installation.

The language is added in the informational note to make it clear that normal service work such as replacing a fuse, circuit breaker or other routine work is generally not considered refurbishing or reconditioning of equipment.
Public Comment No. 707-NFPA 70-2015 [Section No. 110.21(A)(2)]

(2) Reconditioned equipment shall be marked with the name, trademark, or other descriptive marking by which the organization responsible for reconditioning the electrical equipment can be identified, along with the date of the reconditioning.

   Informational Note: Industry standards are available for application of reconditioned and refurbished equipment. Normal servicing of equipment that remains within a facility is not considered to be reconditioned or refurbished.

Statement of Problem and Substantiation for Public Comment

A concern was expressed in the Public Input stage that the new language might be misinterpreted to apply to normal service work like replacing a fuse, circuit breaker or other routine work. The suggested language is added to make it clear that this type of work is not considered refurbishing or reconditioning of equipment.

Committee Statement

Committee Action: Rejected
Resolution: CMP-1 reaffirms its position on FR 42 that incorporation of language the more specifically clarifies that the term equipment refers to all equipment including new or other types. The authority having jurisdiction has approval responsibilities and this language addresses reconditioned equipment and provides a more generalized requirement that AHJs can use as basis for approval. CMP-1 recognizes that the approval processes and means of issuing approvals vary. This language introduced allows the AHJ to accept any method without restriction to one. See SR 9 for further information.
Public Comment No. 1748-NFPA 70-2015 [Section No. 110.24]

110.24 Available Fault Current.

(A) Field Marking.

Service equipment at other than dwelling units shall be legibly marked in the field with the maximum available fault current. The field marking(s) shall include the date the fault-current calculation was performed and be of sufficient durability to withstand the environment involved. The calculation shall be documented and made available to those authorized to design, install, inspect, maintain, and operate the system.

Informational Note: The available fault-current marking(s) addressed in 110.24 is related to required short-circuit current ratings of equipment. NFPA 70E-2012, Standard for Electrical Safety in the Workplace, provides assistance in determining the severity of potential exposure, planning safe work practices, and selecting personal protective equipment.

(B) Modifications.

When modifications to the electrical installation occur that affect the maximum available fault current at the service, the maximum available fault current shall be verified or recalculated as necessary to ensure the service equipment ratings are sufficient for the maximum available fault current at the line terminals of the equipment. The required field marking(s) in 110.24(A) shall be adjusted to reflect the new level of maximum available fault current.

Exception: The field marking requirements in 110.24(A) and 110.24(B) shall not be required in industrial installations where conditions of maintenance and supervision ensure that only qualified persons service the equipment.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs that CMP-1 review its action and verify the correct edition date shown for NFPA 70E in the Informational Note.

Public Comment No. 708-NFPA 70-2015 [Section No. 110.26(A)(4)]

(4) Limited Access.

Where equipment operating at 1000 volts, nominal, or less to ground and likely to require examination, adjustment, servicing, or maintenance while energized is required by installation instructions or function to be located in a space with limited access, all of the following shall apply:

(a) Where equipment is installed above a lay-in ceiling, there shall be an opening not smaller than 559 mm × 559 mm (22 in. × 22 in.), or in a crawl space, there shall be an accessible opening not smaller than 559 mm × 762 mm (22 in. × 30 in.).

(b) The width of the working space shall be the width of the equipment enclosure or a minimum of 762 mm (30 in.), whichever is greater.

(c) All enclosure doors or hinged panels shall be capable of opening a minimum of 90 degrees.

(d) The space in front of the enclosure shall comply with the depth requirements of Table 110.26(A)(1). The maximum height of the working space shall be the height necessary to install the equipment in the limited space. A horizontal ceiling structural member or access panel shall be permitted in this space.

Statement of Problem and Substantiation for Public Comment

The language in the first revision does not indicate why such equipment would be in a space with limited access that does not comply with other Code requirements for adequate working space. The added wording is intended to clarify that the equipment is required to be installed in an area with limited access in order to serve the function for which it is intended or to comply with manufacturer's installation instructions.

Public Comment No. 1568-NFPA 70-2015 [Section No. 110.26(B)]

(B) Clear Spaces.

Working space required by this section shall not be used for storage. When normally enclosed live parts are exposed for inspection or servicing, the working space, if in a passageway or general open space, shall be suitably guarded. Permanent and conspicuous signs shall be provided. The sign shall meet the requirements in 110.21(B) and shall read as follows:

NOTICE
ELECTRICAL EQUIPMENT WORKING SPACE AND
EGRESS AREA — NO OBSTRUCTION OR STORAGE ALLOWED

Statement of Problem and Substantiation for Public Comment

FR-17 should not have been accepted. Additional signage has not been shown to solve the stated problem.

Committee Statement

Committee Action: Rejected but see related SR
Statement: The requirement in the First Draft for signage to be installed in locations that are dedicated to clear space working areas has not been shown to be an effective means of ensuring compliance with the Section. The code does not prohibit the installation of signage at the building owner’s option. It is essential that the requirement for clear space remain in the Code.
(2) Large Equipment.
For equipment rated 1200 amperes or more and over 1.8 m (6 ft) wide that contains overcurrent devices, switching devices, or control devices, there shall be one entrance to and egress from the required working space not less than 610 mm (24 in.) wide and 2.0 m (6 1/2 ft) high at each end of the working space.

A single entrance to and egress from the required working space shall be permitted where either of the conditions in 110.26(C) (2)(a) or (C)(2)(b) is met.

(a) Unobstructed Egress. Where the location permits a continuous and unobstructed way of egress travel, a single entrance to the working space shall be permitted.

(b) Extra Working Space. Where the depth of the working space is twice that required by 110.26(A)(1), a single entrance shall be permitted. It shall be located such that the distance from the equipment to the nearest edge of the entrance is not less than the minimum clear distance specified in Table 110.26(A)(1) for equipment operating at that voltage and in that condition.

For new installations (with the exception of vaults), the primary and secondary egress paths from the space may not include a ladder or other obstruction that impedes access to medical attention. For existing installations, the "second" means of egress from the space, may include a ladder as long as there is a safe landing outside the space where the person may be accessed by medical personnel. The primary means of egress from the space shall be unobstructed for existing installations.

Statement of Problem and Substantiation for Public Comment

The code is not clear whether or not a ladder may be used in the egress path. NFPA 101, Section 40 and Section 7 appear to allow a "fire ladder" in the egress components for an industrial occupancy. Fundamentally, if we're requiring listed panic hardware on the doors so an injured person may escape from the hazard, it seems that we would also want the person to have an unobstructed exit path to seek medical attention. This public input is an attempt to clarify that and make it clear that for new installations, that is the intent. This is not intended to require existing installation to make costly retrofits if they have an unobstructed "primary" means of egress. If both entrances involve the use of a ladder, however, this language would require retrofit of existing installations. The panel stated in response to Public Input 2367 that "The panel recognizes that ladders may be required for entering and exiting locations such as vaults". This response does not clarify the code's intent, here, and in my opinion the code should not remain silent on whether a ladder may be used. Fundamentally, if we're requiring "listed panic hardware", we should make it clear whether or not the panel intends one entrance to have stairs, or both entrances to have stairs as opposed to allowing potentially both entrances to have ladders, thus delaying medical attention if required.

Street Address:
City:
State:
Zip:
Submittal Date: Fri Sep 25 13:24:17 EDT 2015

Committee Statement
Committee Action: Rejected
Resolution: CMP-1 maintains its position with regard to ladders and egress path. Building codes and OSHA regulations address egress paths.
Outdoor. Outdoor installations shall comply with 110.26(E)(2)(a) through (c).

(a) Installation Requirements. Outdoor electrical equipment shall be the following:

(2) Installed

(b) in suitable

(1) in identified enclosures
(2) Protected from accidental contact by unauthorized personnel, or by vehicular traffic
(3) Protected from accidental spillage or leakage from piping systems

(c) Work Space. The working clearance space shall include the zone described in 110.26(A). No architectural appurtenance or other equipment shall be located in this zone.

   Exception to (b): Structural overhangs or roof extensions shall be permitted in this zone.

(d) Dedicated Equipment Space. The space equal to the width and depth of the equipment, and extending from grade to a height of 1.8 m (6 ft) above the equipment, shall be dedicated to the electrical installation. No piping or other equipment foreign to the electrical installation shall be located in this zone.

Statement of Problem and Substantiation for Public Comment

The term suitable is listed in the 2011 NEC Manual of Style as a term which is vague and possibly unenforceable. The term identified in Article 100 as "Recognizable as suitable for the specific purpose, function, use, environment, application, and so forth, where described in a particular Code requirement." By making this proposed change, the requirement eliminates the vague and possibly unenforceable term and replaces it with a term that does not change requirement but is enforceable.

Submittal Date: Fri Sep 25 12:48:23 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-14-NFPA 70-2015
Statement: The vague and possibly unenforceable term “suitable” is replaced with the defined and enforceable term “identified” to comply with the NEC Style Manual and to add consistency throughout the code. Outdoor use enclosures are tested for exclusion of rain, and are inherently protected against accidental spillage or leakage from piping systems. Exclusion of architectural appurtenances is covered in the Exception.
(2) Outdoor.
Outdoor installations shall comply with 110.26(E)(2)(a) through (c).

   (a) **Installation Requirements.** Outdoor electrical equipment shall be the following:

   1. Installed in suitable enclosures
   2. Protected from accidental contact by unauthorized personnel, or by vehicular traffic
   3. Protected from accidental spillage or leakage from piping systems

   (b) **Work Space.** The working clearance space shall include the zone described in 110.26(A). No architectural
appurtenance or other equipment shall be located in this zone.

      *Exception to (b): Structural overhangs or roof extensions shall be permitted in this zone.*

   (c) **Dedicated Equipment Space.** The space equal to the width and depth of the equipment, and extending from grade to
a height of 1.8 m (6 ft) above the equipment, shall be dedicated to the electrical installation. No piping or other equipment
foreign to the electrical installation shall be located in this zone.

Locked Electrical Equipment Rooms or Enclosures.

1. Electrical equipment rooms or enclosures housing electrical apparatus that are controlled by a lock(s) shall be considered accessible to qualified persons.

2. The entrance to all buildings, vaults, rooms, or enclosures containing exposed live parts or exposed conductors operating at 601 to 1000 volts, nominal, shall be kept locked unless such entrances are under the observation of a qualified person at all times. Permanent and conspicuous danger signs shall be provided. The danger sign shall meet the requirements in 110.21(B) and shall read as follows:

   DANGER — HIGH VOLTAGE — KEEP OUT

Statement of Problem and Substantiation for Public Comment

FR-21, which creates an intermediate voltage level requirement that covers 601-1000V, should not have been accepted. This requirement does not need to be carried over from 110.34(C). Suitable guarding of LV parts is already required in 110.27 and addressed directly in 110.27(A). Relocating this requirement and creating an intermediate voltage level of 601-1000V is redundant and may create confusion. This intermediate voltage does not exist in global standards, with which the Code is attempting to correlate. The NEC should make a "clean distinction" that LV is \(< =1000V\) and HV is \(>1000V\).

Submittal Date: Fri Sep 25 14:36:11 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Statement: The first revision added unnecessary requirements for systems operating under 1000 volts, nominal. Creating similar requirements to 110.34(C) for an intermediate voltage level of 601-1000V may create confusion.
Public Comment No. 812-NFPA 70-2015 [Section No. 110.26(F)]

(F) Locked Electrical Equipment Rooms or Enclosures.

(1) -
Electrical equipment rooms or enclosures housing electrical apparatus that are controlled by a lock(s) shall be considered accessible to qualified persons.

(2) -
The entrance to all buildings, vaults, rooms, or enclosures containing exposed live parts or exposed conductors operating at 601 to 1000 volts, nominal, shall be kept locked unless such entrances are under the observation of a qualified person at all times. Permanent and conspicuous danger signs shall be provided. The danger sign shall meet the requirements in 110.21(B) and shall read as follows:

DANGER — HIGH VOLTAGE — KEEP OUT.

Statement of Problem and Substantiation for Public Comment

Return 110.26(F) to 2014 text. The substantiation provided by CMP-1 to support this revision seeks to create a new "gap voltage" to fix a problem that does not exist. As past chair of the CC appointed HV task group, I fully understand the reason for the 1000 volt threshold. There is a significant need for correlation throughout the NEC at 1000 volts. Creating "gap voltage ranges" as a short term solution will most certainly cause confusion. As pointed out in the negative ballot of Mr. Barrios, the intent of this revision is met in the present text of the NEC.

Public Comment No. 709-NFPA 70-2015 [Section No. 110.27(A)]

(A) Live Parts Guarded Against Accidental Contact.

Except as elsewhere required or permitted by this Code, live parts of electrical equipment operating at 50 to 1000 volts, nominal shall be guarded against accidental contact by approved enclosures or by any of the following means:

1. By location in a room, vault, or similar enclosure that is accessible only to qualified persons.
2. By permanent, substantial partitions or screens arranged so that only qualified persons have access to the space within reach of the live parts. Any openings in such partitions or screens shall be sized and located so that persons are not likely to come into accidental contact with the live parts or to bring conducting objects into contact with them.
3. By insulating covers over exposed conductive parts, removable only by qualified persons having access to the space, such that it is possible to expose only one phase or polarity at a time.
4. By location on a balcony, gallery, or platform elevated and arranged so as to exclude unqualified persons.
5. By elevation above the floor or other working surface as follows:
   - A minimum of 2.5 m (8 ft) for 50 to 300 volts between ungrounded conductors
   - A minimum of 2.6 m (8 ft 6 in) for 301 to 600 volts between ungrounded conductors
   - A minimum of 2.62 m (8 ft 7 in) for 601 to 1000 volts between ungrounded conductors

Statement of Problem and Substantiation for Public Comment

It is unclear how list item (3) achieves equal protection, and the committee statement does not adequately explain the new allowance. (My only revision was to cross out list item 3, but for some reason Terra shows list items 4 and 5 crossed out as well. Hopefully it will show up correctly for the committee.)

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-16-NFPA 70-2015
Statement: The requirement in list item (3) is adequately covered by the other parts of this section. Protection of specific equipment is identified by other sections of the code and the applicable product standards. SR 16 removes the item 3 that was added in FR 48.
110.28 Enclosure Types.

Enclosures (other than surrounding fences or walls covered in 110.31) of switchboards, switchgear, panelboards, industrial control panels, motor control centers, meter sockets, enclosed switches, transfer switches, power outlets, circuit breakers, adjustable-speed drive systems, pullout switches, portable power distribution equipment, termination boxes, general-purpose transformers, fire pump controllers, fire pump motors, and motor controllers, rated not over 1000 volts nominal and intended for such locations, shall be marked with an enclosure-type number as shown in Table 110.28.

Table 110.28 shall be used for selecting these enclosures for use in specific locations other than hazardous (classified) locations. The enclosures are not intended to protect against conditions such as condensation, icing, corrosion, or contamination that may occur within the enclosure or enter via the conduit or unsealed openings.

110.31 Enclosure for Electrical Installations.

Electrical installations in a vault, room, or closet or in an area surrounded by a wall, screen, or fence, access to which is controlled by a lock(s) or other approved means, shall be considered to be accessible to qualified persons only. The type of enclosure used in a given case shall be designed and constructed according to the nature and degree of the hazard(s) associated with the installation.

For installations other than equipment as described in 110.31(D), a wall, screen, or fence shall be used to enclose an outdoor electrical installation to deter access by persons who are not qualified. A fence shall not be less than 2.1 m (7 ft) in height or a combination of 1.8 m (6 ft) or more of fence fabric and a 300 mm (1 ft) or more extension utilizing three or more strands of barbed wire or equivalent. The distance from the fence to live parts shall be not less than given in Table 110.31.

Note: For clearances of conductors for specific system voltages and typical BIL ratings, see ANSI, see IEEE, C2-2007 2012, National Electrical Safety Code.

Informational Note: See Article 450 for construction requirements for transformer vaults.

(A) Electrical Vaults.

Where an electrical vault is required or specified for conductors and equipment 110.31(A)(1) to (A)(5) shall apply.

(1) Walls and Roof.

The walls and roof shall be constructed of materials that have adequate structural strength for the conditions, with a minimum fire rating of 3 hours. For the purpose of this section, studs and wallboard construction shall not be permitted.

(2) Floors.

The floors of vaults in contact with the earth shall be of concrete that is not less than 102 mm (4 in.) thick, but where the vault is constructed with a vacant space or other stories below it, the floor shall have adequate structural strength for the load imposed on it and a minimum fire resistance of 3 hours.

(3) Doors.

Each doorway leading into a vault from the building interior shall be provided with a tight-fitting door that has a minimum fire rating of 3 hours. The authority having jurisdiction shall be permitted to require such a door for an exterior wall opening where conditions warrant.

Exceptions to (1), (2), and (3): Where the vault is protected with automatic sprinkler, water spray, carbon dioxide, or halon, construction with a 1-hour rating shall be permitted.

(4) Locks.

Doors shall be equipped with locks, and doors shall be kept locked, with access allowed only to qualified persons. Personnel doors shall swing out and be equipped with panic bars, pressure plates, or other devices that are normally latched but that open under simple pressure.

(5) Transformers.

Where a transformer is installed in a vault as required by Article 450, the vault shall be constructed in accordance with the requirements of Part III of Article 450.

Informational Note No. 2: A typical 3-hour construction is 150 mm (6 in.) thick reinforced concrete.

(B) Indoor Installations.

(1) In Places Accessible to Unqualified Persons.

Indoor electrical installations that are accessible to unqualified persons shall be made with metal-enclosed equipment. Switchgear, transformers, pull boxes, connection boxes, and other similar associated equipment shall be marked with appropriate caution signs. Openings in ventilated dry-type transformers or similar openings in other equipment shall be designed so that foreign objects inserted through these openings are deflected from energized parts.
In Places Accessible to Qualified Persons Only.

Indoor electrical installations considered accessible only to qualified persons in accordance with this section shall comply with 110.34, 110.36, and 490.24.

(C) Outdoor Installations.

(1) In Places Accessible to Unqualified Persons.

Outdoor electrical installations that are open to unqualified persons shall comply with Parts I, II, and III of Article 225.

(2) In Places Accessible to Qualified Persons Only.

Outdoor electrical installations that have exposed live parts shall be accessible to qualified persons only in accordance with the first paragraph of this section and shall comply with 110.34, 110.36, and 490.24.

(D) Enclosed Equipment Accessible to Unqualified Persons.

Ventilating or similar openings in equipment shall be designed such that foreign objects inserted through these openings are deflected from energized parts. Where exposed to physical damage from vehicular traffic, suitable guards shall be provided. Equipment located outdoors and accessible to unqualified persons shall be designed such that exposed nuts or bolts cannot be readily removed, permitting access to live parts. Where equipment is accessible to unqualified persons and the bottom of the enclosure is less than 2.5 m (8 ft) above the floor or grade level, the enclosure door or hinged cover shall be kept locked. Doors and covers of enclosures used solely as pull boxes, splice boxes, or junction boxes shall be locked, bolted, or screwed on. Underground box covers that weigh over 45.4 kg (100 lb) shall meet this requirement.

Committee Statement

Committee Action: Rejected but see related SR
Statement: The references to ANSI/ASTM E119 standard and NFPA 80-2016 in the Informational Note were updated. See SR 19 for change made to footnote to table in 110.31 submitted in PC 39.
Electrical installations in a vault, room, or closet or in an area surrounded by a wall, screen, or fence, access to which is controlled by a lock(s) or other approved means, shall be considered to be accessible to qualified persons only. The type of enclosure used in a given case shall be designed and constructed according to the nature and degree of the hazard(s) associated with the installation.

For installations other than equipment as described in 110.31(D), a wall, screen, or fence shall be used to enclose an outdoor electrical installation to deter access by persons who are not qualified. A fence shall not be less than 2.1 m (7 ft) in height or a combination of 1.8 m (6 ft) or more of chain-link fence fabric and a 300 mm (1 ft) or more extension utilizing three or more strands of barbed wire or equivalent. The distance from the fence to live parts shall be not less than given in Table 110.31.

Note: For clearances of conductors for specific system voltages and typical BIL ratings, see ANSI C2-2007, National Electrical Safety Code.

Informational Note: See Article 450 for construction requirements for transformer vaults.

Statement of Problem and Substantiation for Public Comment

We have developers stating that 4" x 4" knotted agricultural fabric is all that is necessary to comply with this section on solar PV installations. We have had too many incidences of people using this fabric like a ladder, but no reference to require chain-link fabric.

Committee Action: Rejected but see related SR
Statement: The references to ANSI/ASTM E119 standard and NFPA 80-2016 in the Informational Note were updated. See SR 19 for change made to footnote to table in 110.31 submitted in PC 39.
(D) Enclosed Equipment Accessible to Unqualified Persons.

Ventilating or similar openings in equipment shall be designed such that foreign objects inserted through these openings are deflected from energized parts. Where exposed to physical damage from vehicular traffic, suitable guards shall be provided. Equipment located outdoors and accessible to unqualified persons, the general public, shall be designed such that exposed nuts or bolts cannot be readily removed, permitting access to live parts. Where equipment is accessible to unqualified persons, the general public, and the bottom of the enclosure is less than 2.5 m (8 ft) above the floor or grade level, the enclosure door or hinged cover shall be kept locked. Doors and covers of enclosures used solely as pull boxes, splice boxes, or junction boxes shall be locked, bolted, or screwed on. Underground box covers that weigh over 45.4 kg (100 lb) shall meet this requirement.

Statement of Problem and Substantiation for Public Comment

In industrial locations, and other non-public spaces there may be electrical equipment that are accessible by unqualified persons, but not accessible to the general public. The terms general public and unqualified persons are not synonymous. Please consider keeping the term "general public" in this section.

Doors and covers of enclosures used solely as pull boxes, splice boxes, or junction boxes shall be locked, bolted, or screwed on. Underground box covers that weigh over 45.4 kg (100 lb) shall meet this requirement.

Statement of Problem and Substantiation for Public Comment

In the last sentence of (D), the word "shall" is unnecessary. The covers meet the intent of the previous requirement by virtue of their weight, and code users are being informed that this is true. If "shall" remains in the language, it could be erroneously construed to mean that the covers must be locked, bolted or screwed on even if they do weigh over 100 pounds.

</table>

Statement of Problem and Substantiation for Public Comment

In the "Over 35 kV" row, I added a "+" sign between the values to return it to the original text: "2.9 m + 9.5 mm/kV" and "9 ft 6 in. + 0.37 in./kV"

I believe the deletion of the "+" sign was done incorrectly in the FR. (For some reason, Terra would not show the addition of the "+" sign in the revision screen, so I hope the suggested change is clear.)

Committee Action: Rejected but see related SR
Resolution: SR-21-NFPA 70-2015
Statement: These plus signs in the "Over 35kV" row were inadvertently omitted in the FR. The table was revised to clarify the elevation over 35kV.
110.41 Inspections and Tests.

(A) Pre-energization and Operating Tests.
Where required elsewhere in this Code, the complete electrical system design, including settings for protective, switching, and control circuits, shall be prepared in advance and made available on request to the authority having jurisdiction and shall be tested when first installed on-site.

(B) Test Report.
A test report covering the results of the tests required in 110.41(A) shall be available to the authority having jurisdiction prior to energization and made available to those authorized to install, operate, test, and maintain the system.

Statement of Problem and Substantiation for Public Comment

FR-36 should not have been accepted. The proposed new section 110.41 is broad, overly restrictive and falls outside the scope of 90.1(A). There are many elements of a "complete electrical system design" that are not relevant to the practical safeguarding of persons and property from hazards arising from the use of electricity. The proposed text is also unenforceable. Is it the responsibility of the AHJ to review and approve "the complete electrical system design"? The new section also requires the "complete electrical system design" to be tested "when first installed on-site". There are many tests conducted on electrical installations that are not relevant to practical safeguarding of persons and property. Also, testing installations "when first installed" may not be practical, or verify the safety of the installation, especially in the case of large projects that may take several years to install and energize. This new section has the potential of going well beyond the practical safeguarding of persons and property from hazards arising from the use of electricity, and therefore should be deleted.

Committee Statement

Committee Action: Rejected
Resolution: CMP-1 reaffirms the action and statement for FR 36.
### 110.73 Equipment Work Space.

Where electrical equipment with live parts that is likely to require examination, adjustment, servicing, or maintenance while energized is installed in a manhole, vault, or other enclosure designed for personnel access, the work space and associated requirements in 110.26 shall be met for installations operating at 1000 volts or less. Where the installation is over 1000 volts, the work space and associated requirements in 110.34 shall be met. A manhole access cover that weighs over 45 kg (100 lb) shall meet be considered as meeting the requirements of 110.34(C).

### Statement of Problem and Substantiation for Public Comment

As revised, the manhole cover would also need a lock and sign as required in 110.34 (C). The original intent needs to be restored that a manhole access cover weighing over 100 lbs meets the requirement in 110.34(C). Please re-instate the original wording of section 110.73 Equipment Work Space.

Public Comment No. 1177-NFPA 70-2015 [New Section after 210.1]

TITLE OF NEW CONTENT
210.2 Definitions
Unfinished Basements. Portions or areas of a basement not intended as habitable rooms or spaces

Statement of Problem and Substantiation for Public Comment

Including unfinished basements in 210.8(B) has identified sufficient substantiation to define the term "unfinished basement" for the purposes of the 210. This can be accomplished by locating the definition in 210.2 vacated during the First Draft actions. By removing the text "storage areas, work areas, and the like" from 210.8(A)(5) in the First Draft the reference to open areas in basements was lost. This presents enforcement challenges for the inspector. For example; how would a habitable space within a basement that has not been finished as a "room" be treated? The words "or spaces" was added to the end of the proposed definition for clarity and uniform understanding. Companion comments have been submitted to delete the text in 210.8(A) & (B).

Public Comment No. 1176-NFPA 70-2015 [ Section No. 210.1 ]

210.1 Scope.
This article provides the general requirements for branch circuits.

Note since there is no 210.2 in terraview add the following definition.

210.2 Definitions
Laundry Area. Any space within 1.8 m (6 ft) of the nearest edge of a washing machine or dryer.

Statement of Problem and Substantiation for Public Comment

CMP 2 rejected PI No. 3458, which sought to create a definition of a laundry area, stating “Sufficient information or substantiation has not been provided for the panel to conclude that all laundry areas are limited to only six feet from the edge of the laundry equipment. Based on all the various design layouts that the panel discussed it would not be possible to determine where the laundry area begins and ends.” The last sentence of the Panel’s statement is exactly why defining the term is necessary. Currently there is no way for an electrical inspector to provide uniform enforcement of the boundaries for GFCI requirements for receptacle outlets in laundry areas. For example; if there was a studio apartment with a washing machine in one corner of the common area would GFCI protection be required for all the 125 volt, 15 and 20 ampere receptacles? What if a basement has been finished as one large open room but there is a washing machine or dryer in the room, do all the 125 volt, 15 and 20 ampere receptacles in the room require GFCI protection? The substantiation that brought the GFCI requirements for laundry areas in the 2014 NEC was directly related to appliance failures not receptacle outlets in adjacent areas. IAEI panel members did not vote against the addition of the requirement as there was merit to requiring GFCI protection for receptacle outlets adjacent to a washer or dryer which introduce grounded surfaces to the environment. With those thoughts in mind, the 1.8 m (6 ft) measurement makes perfect sense and it should be in any direction. Any receptacle outlets located beyond the traditional reach measurement of 1.8 m (6 ft) should be judged by the specific environment they are located in as contact with the appliance is not likely. If the GFCI protection requirements are really for the appliance and not the environment the receptacle outlet is located in they do not belong in 210.8 and should be moved to 422.5 in the next cycle. Section 210.2 was vacated at the First Draft stage so it was chosen as the location for the new definition. The term “laundry area” is used in other locations in 210 and therefore should be defined for the purpose of the article.

### Statement of Problem and Substantiation for Public Comment

Robert Bosch LLC proposes to add a reference in the table to the new article 712 addressing Direct Current (DC) Microgrids. There are specific branch circuit requirements for DC Microgrids in article 712 that amend or supplements the requirements of this article.

Robert Bosch LLC is actively involved in DC Microgrid pilot installations with the Department of Defense, the California Energy Commission, as well as with building-scale demonstration projects in North Carolina and Michigan. Through this experience, it has become clear that code clarifications are necessary with respect to branch circuits for DC Microgrids and Article 712 is being included to address those issues as well as other issues related to DC use within buildings.

Statement of Problem and Substantiation for Public Comment

Section 210.3 was revised to clarify the application of the table. Other than for listing specific purpose requirements in Chapters 2, 3 & 4, Table 210.3 is not necessary nor is it all inclusive as it exists. Section 90.3 already provides the guidance that specific equipment and applications in Chapters 5, 6 & 7 can amend or supplement the branch circuit requirements in 210 so the sections referencing branch circuit requirements in those Chapters can be removed.

Tables are helpful and benefit readers when they remain all inclusive. However, it would be a challenging task to provide readers with a continually updated list of all the sections that include branch circuit requirements that amend or supplement those in 210 so only the references that do not amend or supplement those in Article 210 via 90.3 were kept.

Public Comment No. 1234-NFPA 70-2015 [ New Section after 210.5(C)(1) ]

(c) For 277/480 volt systems, the wire colors shall be brown, orange and yellow. For 120/208 volt systems, the wire colors shall be black, red and blue.

Statement of Problem and Substantiation for Public Comment

This is used elsewhere in the NEC. This also adds consistency to the installation. The CMP pointed out it was not in mandatory language, so this has been changed to reflect mandatory language.

Committee Statement

Committee Action: Rejected
Resolution: Unique color codes may be used in different geographic areas or within different industrial facilities. The current language provides the flexibility to accommodate these unique applications.
(1) Branch Circuits Supplied from More Than One Nominal Voltage System.

Where the premises wiring system has branch circuits supplied from more than one nominal voltage system, each ungrounded conductor of a branch circuit shall be identified by phase or line and system at all termination, connection, and splice points in compliance with 210.5(C)(1)(a) and (b).

(a) Means of Identification. The means of identification shall be permitted to be by separate color coding, marking tape, tagging, or other approved means.

(b) Posting of Identification Means. The method utilized for conductors originating within each branch-circuit panelboard or similar branch-circuit distribution equipment shall be documented in a manner that is readily available or shall be permanently posted at each branch-circuit panelboard or similar branch-circuit distribution equipment. The label shall be of sufficient durability to withstand the environment involved and shall not be handwritten.

Exception: In existing installations where a voltage system(s) already exists and a different voltage system is being added, it is permissible to mark only the new system voltage. Existing unidentified systems shall not be required to be identified at each termination, connection, and splice point in compliance with 210.5(C)(1)(a) and (b). Labeling is required at each voltage system distribution equipment to identify that only one voltage system has been marked for a new system(s). The new system label(s) shall include the words "Other unidentified systems exist on the premises."

Statement of Problem and Substantiation for Public Comment

The First Draft language is not clear and therefore presents installation and enforcement challenges. The proposed text will clarify the existing unidentified installations must have been made prior to the adoption of the 2005 NEC, when 210.5(C) first appeared, to be excluded from new system identifications and where that identification is required. Providing the specific minimum specific wording will preserve the intent of the change while promoting consistency in installations and inspections.

Resolution: SR-304-NFPA 70-2015
Statement: The revised text clarifies that the existing unidentified installations must have been made prior to the adoption of the 2005 NEC, when 210.5(C) first appeared, to be excluded from new system identifications and where that identification is required.
Public Comment No. 1653-NFPA 70-2015 [Sections 210.5(C)(1), 210.5(C)(2)]

Sections 210.5(C)(1), 210.5(C)(2)

(1) Branch Circuits Supplied from More Than One Nominal Voltage System.

Where the premises wiring system has branch circuits supplied from more than one nominal voltage system, each ungrounded conductor of a branch circuit shall be identified by phase or line and system at all termination, connection, and splice points in compliance with 210.5(C)(1)(a) and (b).

(a) Means of Identification. The means of identification shall be permitted to be by separate color coding, marking tape, tagging, or other approved means.

(b) Posting of Identification Means. The method utilized for conductors originating within each branch-circuit panelboard or similar branch-circuit distribution equipment shall be documented in a manner that is readily available or shall be permanently posted at each branch-circuit panelboard or similar branch-circuit distribution equipment. The label shall be of sufficient durability to withstand the environment involved and shall not be handwritten.

Exception: In existing installations where a voltage system(s) already exists and a different voltage system is being added, it is permissible to mark only the new system voltage at each termination, connection, and splice point in compliance with 210.5(C)(1)(a) and (b). Labeling is required at each voltage system distribution equipment to identify that only one voltage system has been marked.

(2) Branch Circuits Supplied from Direct-Current Systems.

Where a branch circuit is supplied from a dc system operating at more than 60 volts, each ungrounded conductor of 4 AWG or larger shall be identified by polarity at all termination, connection, and splice points by marking tape, tagging, or other approved means; each ungrounded conductor of 6 AWG or smaller shall be identified by polarity at all termination, connection, and splice points in compliance with 210.5(C)(2)(a) and (b). The identification methods utilized for conductors originating within each branch-circuit panelboard or similar branch-circuit distribution equipment shall be documented in a manner that is readily available or shall be permanently posted at each branch-circuit panelboard or similar branch-circuit distribution equipment.

(a) Positive Polarity, Sizes 6 AWG or Smaller. Where the positive polarity of a dc system does not serve as the connection point for the grounded conductor, each positive ungrounded conductor shall be identified by one of the following means:

(1) A continuous red outer finish

(2) A continuous red stripe durably marked along the conductor’s entire length on insulation of a color other than green, white, gray, or black

(3) Imprinted plus signs (+)

(b) Negative Polarity, Sizes 6 AWG or Smaller. Where the negative polarity of a dc system does not serve as the connection point for the grounded conductor, each negative ungrounded conductor shall be identified by one of the following means:

(1) A continuous black outer finish

(2) A continuous black stripe durably marked along the conductor’s entire length on insulation of a color other than green, white, gray, or red

(3) Imprinted minus signs (–) or the word NEGATIVE or NEG durably marked on insulation of a color other than green, white, gray, or red and repeated at intervals not exceeding 610 mm (24 in.) in accordance with 310.120(B)

Statement of Problem and Substantiation for Public Comment

The Code requires continuous identification of ungrounded dc conductors via markings every 24”. This puts undue financial burden on retrofit installations.

The EMerge Alliance proposes to allow the re-use of existing conductors in retrofit situations through suitable marking means as accepted elsewhere in the Code.

We do not believe there will be any adverse safety risk caused by this change.

The previously accepted exception to 210.5(C)1 in FR 302 above should apply to 210.5(C)2, with suitable contextual wording changes.

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-305-NFPA 70-2015
Statement: An additional list item is added to the identification means of positive and negative polarity conductors. This addition supports the re-use of branch conductors for dc applications.
210.5(C)(2) was a new requirement in the 2014 NEC. It was a positive step forward in requiring clear identification of dc wiring and its polarity. Looking forward, a large part of the application of dc microgrids (see Article 712) and the LED retrofit business will involve dc power distribution through existing branch circuits. The 2014 Code did not consider this re-use case for marking, and essentially requires new cable to be pulled when a modern permanent marking method such as printed heat shrink sleeves would be quite adequate. This change is proposed in order to support this emerging, environmentally important LED retrofit industry. It allows marking by up to date, permanent means (e.g. heat shrink sleeve), and re-use of branch conductors for dc lighting and dc microgrid applications.

Note Terraview is wrongly changing numbering - in both cases this becomes a part (4). It also takes the (+) sign out from between the parens in the first addition.

Regarding the safety of re-use of 277 Vac branch circuits for dc applications, building wire is typically rated for 600V ac and dc. The nominal voltage to ground of most dc microgrids is 190 Vdc (380 V center-resistively grounded). This imparts significantly less stress on insulation than 277 Vac which impresses \(277 \times \sqrt{2} = 390\) Vpeak to ground. Ungrounded dc microgrid systems are also required to have ground fault protection by both articles 250 and 712.

(2) Branch Circuits Supplied from Direct-Current Systems.

Where a branch circuit is supplied from a dc system operating at more than 60 volts, each ungrounded conductor of 4 AWG or larger shall be identified by polarity at all termination, connection, and splice points by marking tape, tagging, or other approved means; each ungrounded conductor of 6 AWG or smaller shall be identified by polarity at all termination, connection, and splice points in compliance with 210.5(C)(2)(a) and (b). The identification methods utilized for conductors originating within each branch-circuit panelboard or similar branch-circuit distribution equipment shall be documented in a manner that is readily available or shall be permanently posted at each branch-circuit panelboard or similar branch-circuit distribution equipment.

(a) Positive Polarity, Sizes 6 AWG or Smaller. Where the positive polarity of a dc system does not serve as the connection point for the grounded conductor, each positive ungrounded conductor shall be identified by one of the following means:

(2) A continuous red outer finish

(3) A continuous red stripe durably marked along the conductor's entire length on insulation of a color other than green, white, gray, or black

(4) Imprinted plus signs (+)

±

(1) or the word POSITIVE or POS durably marked on insulation of a color other than green, white, gray, or black and repeated at intervals not exceeding 610 mm (24 in.) in accordance with 310.120(B)

(2) In retrofit work, a permanent sleeve or tube marked /POSITIVE/POS at all splices and terminations shall be permitted

(e) Negative Polarity, Sizes 6 AWG or Smaller. Where the negative polarity of a dc system does not serve as the connection point for the grounded conductor, each negative ungrounded conductor shall be identified by one of the following means:

(1) A continuous black outer finish

(2) A continuous black stripe durably marked along the conductor's entire length on insulation of a color other than green, white, gray, or red

(3) Imprinted minus signs (−) or the word NEGATIVE or NEG durably marked on insulation of a color other than green, white, gray, or red and repeated at intervals not exceeding 610 mm (24 in.) in accordance with 310.120(B)

(4) In retrofit work, a permanent sleeve or tube marked -/NEGATIVE/NEG at all splices and terminations shall be permitted

Statement of Problem and Substantiation for Public Comment

There is increasing interest in retrofitting DC microgrids into buildings for improved energy efficiency, reliability, and self-generation of power from e.g. solar. The proposed change will provide a safe, permanent means of marking DC circuits without pulling new wire.

(1) A continuous black outer finish

(2) A continuous black stripe durably marked along the conductor’s entire length on insulation of a color other than green, white, gray, or red

(3) Imprinted minus signs (–) or the word NEGATIVE or NEG durably marked on insulation of a color other than green, white, gray, or red and repeated at intervals not exceeding 610 mm (24 in.) in accordance with 310.120(B)

Statement of Problem and Substantiation for Public Comment

Robert Bosch LLC (Bosch) proposes an amendment to Article 210.5(C)(2). This amendment clarifies how existing wiring circuits in buildings being converted to a dc system will be identified.

The reason for this amendment is that existing ungrounded conductors of 6 AWG or smaller in buildings being converted to a dc system can also be safely reused and identified per the same requirements as ungrounded conductors of 4 AWG or larger without any safety or reliability concerns. It is reasonable for the present requirements for 6 AWG or smaller in Article 210.5(C)(2)(a) and (b) to apply to new building construction, however for existing buildings it would in essence require perfectly usable existing wiring to be removed/disposed of and new wiring to be installed. This adds extra unnecessary waste/cost with the potential to create a less reliable and safe wiring environment through the extensive rework necessary, for zero benefit as the existing wiring does not need replacement and can be properly identified. The retrofit of specific existing wiring circuits to operate on a dc system, such as lighting circuits in commercial buildings, rather than having to install new wiring represents a tremendous improvement in utilization of renewable energy, overall system reliability, and resiliency to power outages with long-term cost effective savings and no impact to safety and reliability. Conversion to DC circuits also offers the opportunity to utilize high-resistance midpoint grounding schemes, which substantially reduces the chances of electric shock, since both current-carrying conductors have a high-resistance path to ground in this configuration.

Committee Action: Rejected but see related SR
Statement: This revision removes the redundant reference to "devices and equipment."
210.8 Ground-Fault Circuit-Interrupter Protection for Personnel.

Ground-fault circuit-interrupter protection for personnel shall be provided as required in 210.8(A) and 210.8(B). The ground-fault circuit interrupter shall be installed in a readily accessible location.

Informational Note No. 1: See 215.9 for ground-fault circuit-interrupter protection for personnel on feeders.

Informational Note No. 2: See 422.5(A) for GFCI requirements for appliances.

For the purposes of this section, when determining distance from receptacles the distance shall be measured as the shortest path the cord of an appliance connected to the receptacle would follow without piercing a floor, wall, ceiling, or fixed barrier, or passing through a door, doorway, or window.

(A) Dwelling Units.

All 125- and 250-volt, single-phase, 15- and 20-ampere receptacles installed in the locations specified in 210.8(A) (1) through (10) shall have ground-fault circuit-interrupter protection for personnel.

(1) Bathrooms

(2) Garages, and also accessory buildings that have a floor located at or below grade level not intended as habitable rooms and limited to storage areas, work areas, and areas of similar use

(3) Outdoors

Exception to (3): Receptacles that are not readily accessible and are supplied by a branch circuit dedicated to electric snow-melting, deicing, or pipeline and vessel heating equipment shall be permitted to be installed in accordance with 426.28 or 427.22, as applicable.

(4) Crawl spaces — at or below grade level

(5) Unfinished basements — for purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms

Exception to (5): A receptacle supplying only a permanently installed fire alarm or burglar alarm system shall not be required to have ground-fault circuit-interrupter protection.

Informational Note: See 760.41(B) and 760.121(B) for power supply requirements for fire alarm systems.

Receptacles installed under the exception to 210.8(A) (5) shall not be considered as meeting the requirements of 210.52(G).

(6) Kitchens — where the receptacles are installed to serve the countertop surfaces

(7) Sinks — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the sink

(8) Boathouses

(9) Bathtubs or shower stalls — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the bathtub or shower stall

(10) Laundry areas

(B) Other Than Dwelling Units.

All 125-volt, single-phase, 15- and 20-ampere receptacles installed in the locations specified in 210.8(B)(1) through (8) shall have ground-fault circuit-interrupter protection for personnel.

(1) Class A Ground-Fault Circuit-Interrupter Protection (GFCI).

(a) All single-phase receptacles rated 150 volts to ground or less, 50 amperes or less, shall have GFCI protection for personnel.

(b) All three-phase receptacles rated 150 volts to ground or less, 100 amperes or less, shall have GFCI protection for personnel.

(2) Classes C, D, or E Special-Purpose Ground-Fault Circuit-Interrupter Protection (SPGFCI).

(a) All single-phase receptacles rated more than 150 volts to ground and up to 600 volts between ungrounded conductors, 100 amperes or less, shall have special-purpose ground-fault circuit-interrupter (SPGFCI) protection for personnel.

(b) All three-phase receptacles rated more than 150 volts to ground and up to 600 volts between ungrounded conductors, 100 amperes or less, shall have special-purpose ground-fault circuit-interrupter (SPGFCI) protection for personnel.
(3) Locations.

(a) Bathrooms  (b) Kitchens  (c) Rooftops

(d) Outdoors

Exception No. 1 to (c) and (d): Receptacles that are not readily accessible and are supplied by a branch circuit dedicated
to electric snow-melting, deicing, or pipeline and vessel heating equipment shall be permitted to be installed in accordance
with 426.28 or 427.22, as applicable.

Exception No. 2 to (d): In industrial establishments only, where the conditions of maintenance and supervision ensure
that only qualified personnel are involved, an assured equipment grounding conductor program as specified in 590.6(B)(2)
shall be permitted for only those receptacle outlets used to supply equipment that would create a greater hazard if power is
interrupted or having a design that is not compatible with GFCI protection.

(e) Sinks — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the sink

Exception No. 1 to (e): In industrial laboratories, receptacles used to supply equipment where removal of power would
introduce a greater hazard shall be permitted to be installed without GFCI protection.

Exception No. 2 to (e): For receptacles located in patient bed locations of general care or critical care areas of health
care facilities other than those covered under 210.8(B) (1), GFCI protection shall not be required.

(f) Indoor wet locations  (g) Locker rooms with associated showering facilities

(h) Garages, service bays, and similar areas other than vehicle exhibition halls and showrooms

(i) Crawl spaces — GFCI protection shall be provided for lighting outlets in crawl spaces at or below grade level.

(j) Unfinished basements — for the purposes of this section, unfinished basements are defined as portions or areas of
the basement not intended as habitable rooms.

---

Statement of Problem and Substantiation for Public Comment

The Correlating Committee additionally directs that FR 4247 be sent to Code-Making Panel 2 for additional action with regard to the use
of “general” and “critical care areas” in 210.8.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-322-NFPA 70-2015
Statement: The requirement for the Class C, D or E special purpose ground fault circuit Interrupter protection was deleted because
of a concern for the improper application of this solution as well as insufficient substantiation to support expanding the
requirement to these circuits.

An editorial change was made by deleting “locations” section and the sections renumbered as it was necessary due to
the deletion of the items (1) and (2) of this section.

The rooftop exception was re-instated to clarify when the receptacle needs to be readily accessible.

The text regarding sinks has been revised to clarify how the measurement is made.

Patient care categories were added to correlate with Article 517 and NFPA 99.

The text regarding unfinished basements has been revised such that a definition for unfinished basements is
unnecessary.
210.8  Ground-Fault Circuit-Interrupter Protection for Personnel.

Ground-fault circuit-interrupter protection for personnel shall be provided as required in 210.8(A) and 210.8(B). The ground-fault circuit interrupter shall be installed in a readily accessible location.

Informational Note No. 1: See 215.9 for ground-fault circuit-interrupter protection for personnel on feeders.

Informational Note No. 2: See 422.5(A) for GFCI requirements for appliances.

For the purposes of this section, when determining distance from receptacles the distance shall be measured as the shortest path the cord of an appliance connected to the receptacle would follow without piercing a floor, wall, ceiling, or fixed barrier, or passing through a door, doorway, or window.

(A)  Dwelling Units.

All 125- and 250-volt, single-phase, 15- and 20-ampere receptacles installed in the locations specified in 210.8(A)(1) through (10) shall have ground-fault circuit-interrupter protection for personnel.

1) Bathrooms

2) Garages, and also accessory buildings that have a floor located at or below grade level not intended as habitable rooms and limited to storage areas, work areas, and areas of similar use

3) Outdoors

   Exception to (3): Receptacles that are not readily accessible and are supplied by a branch circuit dedicated to electric snow-melting, deicing, or pipeline and vessel heating equipment shall be permitted to be installed in accordance with 426.28 or 427.22 as applicable.

4) Crawl spaces — at or below grade level

5) Unfinished basements — for purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms

   Exception to (5): A receptacle supplying only a permanently installed fire alarm or burglar alarm system shall not be required to have ground-fault circuit-interrupter protection.

Informational Note: See 760.41(B) and 760.121(B) for power supply requirements for fire alarm systems.

Receptacles installed under the exception to 210.8(A)(5) shall not be considered as meeting the requirements of 210.52(G).

6) Kitchens — where the receptacles are installed to serve the countertop surfaces

7) Sinks — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the sink

8) Boathouses

9) Bathubs or shower stalls — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the bathtub or shower stall

10) Laundry areas

(B)  Other Than Dwelling Units.

All 125-volt, single-phase, 15- and 20-ampere receptacles installed in the locations specified in 210.8(B)(1) through (8) shall have ground-fault circuit-interrupter protection for personnel.

   a) All single-phase receptacles rated 150 volts to ground or less, 50 amperes or less, shall have GFCI protection for personnel,

   b) All three-phase receptacles rated 150 volts to ground or less, 100 amperes or less, shall have GFCI protection for personnel.

2) Classes C, D, or E Special-Purpose Ground-Fault Circuit-Interrupter Protection (SPGFCI).

   a) All single-phase receptacles rated more than 150 volts to ground and up to 600 volts between ungrounded conductors, 100 amperes or less, shall have special-purpose ground-fault circuit-interrupter (SPGFCI) protection for personnel.

   b) All three-phase receptacles rated more than 150 volts to ground and up to 600 volts between ungrounded conductors, 100 amperes or less, shall have special-purpose ground-fault circuit-interrupter (SPGFCI) protection for personnel.
(3) Locations.

(a) Bathrooms  
(b) Kitchens  
(c) Rooftops  

(d) Outdoors

Exception No. 1 to (c) and (d): Receptacles that are not readily accessible and are supplied by a branch circuit dedicated to electric snow-melting, deicing, or pipeline and vessel heating equipment shall be permitted to be installed in accordance with 426.28 or 427.22, as applicable.

Exception No. 2 to (d): In industrial establishments only, where the conditions of maintenance and supervision ensure that only qualified personnel are involved, an assured equipment grounding conductor program as specified in 590.6(B)(2) shall be permitted for only those receptacle outlets used to supply equipment that would create a greater hazard if power is interrupted or having a design that is not compatible with GFCI protection.

(e) Sinks — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the sink

Exception No. 1 to (e): In industrial laboratories, receptacles used to supply equipment where removal of power would introduce a greater hazard shall be permitted to be installed without GFCI protection.

Exception No. 2 to (e): For receptacles located in patient bed locations of general care or critical care areas of health care facilities other than those covered under 210.8(B) (1), GFCI protection shall not be required.

(f) Indoor wet locations  
(g) Locker rooms with associated showering facilities  

(h) Garages, service bays, and similar areas other than vehicle exhibition halls and showrooms  

(i) Crawl spaces — GFCI protection shall be provided for lighting outlets in crawl spaces at or below grade level.  

(j) Unfinished basements — for the purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms.

(k) **[C] Boat Hoists.** GFCI protection shall be provided for outlets not exceeding 240 volts that supply boat hoists installed in dwelling unit locations.

### Statement of Problem and Substantiation for Public Comment

The 2014 NEC addresses the hazard associate with boat hoists beginning with the outlet serving the boat hoist up to 240V. Protection is not limited to just protecting the “appliance.” There can be cord and plug connected boat hoists. A hazard may exist when inserting or removing the plug from the receptacle, therefore the protection needs to be in the branch circuit. Since the protection needs to remain in the branch circuit the requirement in the NEC must remain in 210.8. 210.8(C) should not be moved to Article 422.

### Committee Statement

Committee Action: Rejected but see related SR

Resolution: Moving this requirement to Article 422 (providing the option for appliances equipped with GFCI protection to meet this requirement) would reduce the existing protection afforded by the NEC

Statement: GFCI protection for boat hoists and dishwashers needs to remain in the branch circuit or outlet. Section 422.5 First Revisions allow the option of providing GFCI protection for boat hoists and dishwashers in the attachment plug, the supply cord or installed within the appliance. There is no UL standard that requires GFCI protection integral with appliances or their cords. For new construction, GFCI protection afforded in the outlet or in the circuit breaker is the best solution for safety as this solution pays no regard to whether or not GFCI protection is provided for in the cord of the appliance.
210.8 Ground-Fault Circuit-Interrupter Protection for Personnel.

Ground-fault circuit-interrupter protection for personnel shall be provided as required in 210.8(A) and 210.8(B). The ground-fault circuit interrupter shall be installed in a readily accessible location.

Informational Note No. 1: See 215.9 for ground-fault circuit-interrupter protection for personnel on feeders.

Informational Note No. 2: See 422.5(A) for GFCI requirements for appliances.

For the purposes of this section, when determining distance from receptacles the distance shall be measured as the shortest path the cord of an appliance connected to the receptacle would follow without piercing a floor, wall, ceiling, or fixed barrier, or passing through a door, doorway, or cabinet opening or window.

(A) Dwelling Units.

All 125- and 250-volt, single-phase, 15- and 20-ampere receptacles installed in the locations specified in 210.8(A)(1) through (10) shall have ground-fault circuit-interrupter protection for personnel.

1. Bathrooms
2. Garages, and also accessory buildings that have a floor located at or below grade level not intended as habitable rooms and limited to storage areas, work areas, and areas of similar use
3. Outdoors
   Exception to (3): Receptacles that are not readily accessible and are supplied by a branch circuit dedicated to electric snow-melting, deicing, or pipeline and vessel heating equipment shall be permitted to be installed in accordance with 426.28 or 427.22, as applicable.
4. Crawls spaces — at or below grade level
5. Unfinished basements — for purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms
   Exception to (5): A receptacle supplying only a permanently installed fire alarm or burglar alarm system shall not be required to have ground-fault circuit-interrupter protection.

Informational Note: See 760.41(B) and 760.121(B) for power supply requirements for fire alarm systems.

Receptacles installed under the exception to 210.8(A)(5) shall not be considered as meeting the requirements of 210.52(G).

6. Kitchens — where the receptacles are installed to serve the countertop surfaces
7. Sinks — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the sink
8. Boathouses
9. Bathubs or shower stalls — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the bathtub or shower stall
10. Laundry areas

(B) Other Than Dwelling Units.

All 125-volt, single-phase, 15- and 20-ampere receptacles installed in the locations specified in 210.8(B)(1) through (8) shall have ground-fault circuit-interrupter protection for personnel.

   (a) All single-phase receptacles rated 150 volts to ground or less, 50 amperes or less, shall have GFCI protection for personnel,
   (b) All three-phase receptacles rated 150 volts to ground or less, 100 amperes or less, shall have GFCI protection for personnel.

2. Classes C, D, or E Special-Purpose Ground-Fault Circuit-Interrupter Protection (SPGFCI).
   (a) All single-phase receptacles rated more than 150 volts to ground and up to 600 volts between ungrounded conductors, 100 amperes or less, shall have special-purpose ground-fault circuit-interrupter (SPGFCI) protection for personnel.
   (b) All three-phase receptacles rated more than 150 volts to ground and up to 600 volts between ungrounded conductors, 100 amperes or less, shall have special-purpose ground-fault circuit-interrupter (SPGFCI) protection for personnel.
Locations.

(a) Bathrooms  (b) Kitchens  (c) Rooftops
(d) Outdoors

Exception No. 1 to (c) and (d): Receptacles that are not readily accessible and are supplied by a branch circuit dedicated to electric snow-melting, deicing, or pipeline and vessel heating equipment shall be permitted to be installed in accordance with 426.28 or 427.22, as applicable.

Exception No. 2 to (d): In industrial establishments only, where the conditions of maintenance and supervision ensure that only qualified personnel are involved, an assured equipment grounding conductor program as specified in 590.6(B)(2) shall be permitted for only those receptacle outlets used to supply equipment that would create a greater hazard if power is interrupted or having a design that is not compatible with GFCI protection.

(e) Sinks — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the sink

Exception No. 1 to (e): In industrial laboratories, receptacles used to supply equipment where removal of power would introduce a greater hazard shall be permitted to be installed without GFCI protection.

Exception No. 2 to (e): For receptacles located in patient bed locations of general care or critical care areas of health care facilities other than those covered under 210.8(B) (1), GFCI protection shall not be required.

(f) Indoor wet locations  (g) Locker rooms with associated showering facilities

(h) Garages, service bays, and similar areas other than vehicle exhibition halls and showrooms

(i) Crawl spaces — GFCI protection shall be provided for lighting outlets in crawl spaces at or below grade level.

(j) Unfinished basements — for the purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms.

Statement of Problem and Substantiation for Public Comment

The term “cabinet opening” was added to the new second paragraph to clarify measurements are not made through cabinet openings. This clarification is in response to several questions as to whether cabinet openings were included during the IAEI Section meeting presentations.

Statement of Problem and Substantiation for Public Comment

there are other openings used in the field such as a "cased" and "shadowbox" openings. If these openings are not included, the measurement could extent into other rooms, of course if this is the panels intent this language should not be included.

(10) Laundry areas

Statement of Problem and Substantiation for Public Comment

This comment would seek to return the parent text of 210.8(A) to the original text at 210.8(A) of the 2014 NEC. Where is the substantiation for including 250-volt receptacles in required GFCI protection? No one is more supportive and committed to GFCI protection than the submitter of this comment, but I don't see the required substantiation for this increase. In the Public Input that spurred this proposed change (PI 516), the submitter made a statement about 250 volt air compressors, chop saws, table saws etc. that are widely used in residential areas that see potential hazards from ground faults. This is a statement, not substantiated evidence of these alleged ground faults. Speaking as an experienced woodworker, the 250 volt air compressors chop saws, and table saws that I encounter (especially at dwelling units) are also rated at 30-amperes or greater. If these tools addressed in the public input are rated at 250-volts, they typically would not be covered by these GFCI requirements as they are typically plugged into a 30-ampere rated receptacle (not requiring GFCI protection). Even as currently proposed by FR 346, 210.8(A) would only apply to 15- and 20-ampere rated receptacles. The proposed change would increase the voltage rating, not the ampere rating of the receptacle.

A quick fix to this would be for CMP-2 to simply raise both the voltage rating (to 250 volts) and the ampere rating (to 30 ampere) for the receptacle involved, but once again I ask, where is the substantiation? If the ampere rating were to be increased for GFCI protection, this would encompass such things as the clothes dryer receptacle. Where is the substantiation for a 250-volt, 30-ampere rated clothes dryer to be GFCI protected?

If this section remains as proposed, it will be very difficult for an AHJ to explain why a 250-volt, 20-ampere rated receptacle does not require GFCI protection and a 250-volt, 30-ampere rated receptacle does not require GFCI protection.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-316-NFPA 70-2015
Statement:
The requirement for 250 volt ground fault protection was deleted because there was insufficient substantiation to support expanding the requirement to these circuits.

The text regarding unfinished basements has been revised such that a definition for unfinished basements is unnecessary.

The text regarding sinks has been revised to clarify how the measurement is made.
**Public Comment No. 1236-NFPA 70-2015 [ Section No. 210.8(A) ]**

(A) Dwelling Units.

All 125- and 250-volt, single-phase, 15- and 20-ampere receptacles installed in the locations specified in 210.8(A) (1) through (10) shall have ground-fault circuit-interrupter protection for personnel.

(1) Bathrooms

(2) Garages, and also accessory buildings that have a floor located at or below grade level not intended as habitable rooms and limited to storage areas, work areas, and areas of similar use

(3) Outdoors

Exception to (3): Receptacles that are not readily accessible and are supplied by a branch circuit dedicated to electric snow-melting, deicing, or pipeline and vessel heating equipment shall be permitted to be installed in accordance with 426.28 or 427.22, as applicable.

(4) Crawl spaces — at or below grade level

(5) Unfinished basements — for purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms

---

Exception to

Exceptions to (5):

1. A receptacle supplying only a permanently installed fire alarm or burglar alarm system shall not be required to have ground-fault circuit-interrupter protection.

2. Ground-fault circuit-interrupter protection shall not be required for a single receptacle providing power for sump or sewage pumps where an accessible ground-fault circuit-interrupter protected receptacle is located within 900 mm (3 ft) of the non-GFCI protected receptacle.

   Informational Note: See 760.41(B) and 760.121(B) for power supply requirements for fire alarm systems.

Receptacles installed under the exception to 210.8(A) (5) shall not be considered as meeting the requirements of 210.52(G).

(6) Kitchens — where the receptacles are installed to serve the countertop surfaces

(7) Sinks — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the sink

(8) Boathouses

(9) Bathtubs or shower stalls — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the bathtub or shower stall

(10) Laundry areas

---

**Statement of Problem and Substantiation for Public Comment**

This adds a second exception to item (5). The CMP indicated that no technical substantiation was provided. It is common sense that if a wet condition operates the GFCI and shunts the power to a sump pump, the sump pump will not do its job to remove the water. This will provide a reliable power source for an emergency sump operation while still providing GFI protected convenience outlet for the occupant.

Here is an example of the problem. This is an excerpt from the Louisiana State Uniform Construction Code Councils’ sub committee reviewing the 2014 NEC for possible adoption. This excerpt is from their March 3, 2015 public hearing:

"Committee member Mr. John Stephens from Stephens Contracting Company Inc. testified his company receives numerous calls, concerning nuisance trips, on private sewage treatment plants with sump pumps. They keep sending men out at a cost of $85 per trip to reset the GFCI circuit and they can never determine the cause. Committee member Mr. Ronnie Joundot with Joundot Electric testified his company had also experienced numerous calls concerning nuisance trips on these same type of installations. Discussion followed with several individuals from both the inspection and private sector testifying they had experienced the same issues in the past. The discussion lasted for approximately 1 hour before the issue was tabled for a later meeting to allow the committee to proceed with other sections of the code." The issue was tabled and the review committee sent it forward with the request for the entire LSUCCC to consider some type of amendment addressing the GFCI issues on private sewage treatment plants, refrigerators and dishwashers.

Consideration should be given to amending the NEC to add this exception.

### Committee Statement

- **Committee Action:** Rejected
- **Resolution:** Sufficient substantiation has not been provided to support this change. Listed sump and sewage pumps are compatible with listed GFCI devices.
Public Comment No. 545-NFPA 70-2015 [Section No. 210.8(A)]

(A) Dwelling Units.

All 125- and through 250-volt, single-phase, 15- and 20-ampere receptacles installed in the locations specified in 210.8(A) (1) through (10) shall have ground-fault circuit-interrupter protection for personnel.

(1) Bathrooms

(2) Garages, and also accessory buildings that have a floor located at or below grade level not intended as habitable rooms and limited to storage areas, work areas, and areas of similar use

(3) Outdoors

Exception to (3): Receptacles that are not readily accessible and are supplied by a branch circuit dedicated to electric snow-melting, deicing, or pipeline and vessel heating equipment shall be permitted to be installed in accordance with 426.28 or 427.22, as applicable.

(4) Crawl spaces — at or below grade level

(5) Unfinished basements — for purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms

Exception to (5): A receptacle supplying only a permanently installed fire alarm or burglar alarm system shall not be required to have ground-fault circuit-interrupter protection.

Informational Note: See 760.41(B) and 760.121(B) for power supply requirements for fire alarm systems.

Receptacles installed under the exception to 210.8(A) (5) shall not be considered as meeting the requirements of 210.52(G).

(6) Kitchens — where the receptacles are installed to serve the countertop surfaces

(7) Sinks — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the sink

(8) Boathouses

(9) Bathtubs or shower stalls — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the bathtub or shower stall

(10) Laundry areas

Statement of Problem and Substantiation for Public Comment

Contrary to the panel statement this section was amended by other PI's to include 250v circuits, however it neglected to act on the ampacity of the circuit as addressed in PI 2803. The notion that a 25 ampere circuit is less dangerous than a 20 ampere circuit have been dismissed, pool pump motors are a good example of this. When deciding to require 250v GFCI protection for the pool pumps the panel recognized ampere capacity whether 20 amps or 25 amps had no bearing. Please reconsider the ampacity limitation as a 220v 20 amp compressor next to a sink is no different than a 220v 25 amp compressor. The panel recognized this hazard in the 2017 NEC section 210.8(B). I would hope the same safety concerns are given to homeowner. As far as the voltage is concerned the Panel should consider larger home that have 208/120 three phase services and amend the language to 120 through 250volts.

   Exception to (3): Receptacles that are not readily accessible and are supplied by a branch circuit dedicated to electric snow-melting, deicing, or pipeline and vessel heating equipment shall be permitted to be installed in accordance with 426.28 or 427.22, as applicable.
(4) Crawl spaces — at or below grade level
(5) Unfinished basements — for purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms
   Exception to (5): A receptacle supplying only a permanently installed fire alarm or burglar alarm system shall not be required to have ground-fault circuit-interrupter protection.

Informational Note: See 760.41(B) and 760.121(B) for power supply requirements for fire alarm systems.

Receptacles installed under the exception to 210.8(A) (5) shall not be considered as meeting the requirements of 210.52(G).
(6) Kitchens — where the receptacles are installed to serve the countertop surfaces
(7) Sinks — where receptacles are installed within 1.8 m (6 ft) of the outside top inside edge of the sink bowl
(8) Boathouses
(9) Bathubs or shower stalls — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the bathtub or shower stall
(10) Laundry areas

Statement of Problem and Substantiation for Public Comment

This is a three dimensional product INSIDE, OUTSIDE TOP AND BOTTOM, it should be clear the measurement is taken from the top of the sink. Some stone sinks and free standing sinks are completely exposed and in the case of a drop in sink the outside edge could mean the bottom. If the top inside reference it would be clearer, the measurement starts on the top of the sink along the inside edge of the bowl.

(8) Boathouses

(9) Bathtubs or shower stalls — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the bathtub or shower stall

(10) Laundry areas

Statement of Problem and Substantiation for Public Comment

IEC's position is to delete the requirement for 250 volt GFCI protection in 210.8(A) - (FR 346)

The submitter of PI 516 was concerned about portable power tools and identified tools such as air compressors, chop saws, and tablesaws. For residential applications these tools are typically 120 volt and already covered by current Code requirements. If 250 volt tools are utilized in a dwelling unit then the GFCI protection should be located in the article covering the specific equipment.

There is no significant substantiation to expand GFCI protection to 250-volt, single phase, 15- and 20-ampere receptacles in dwelling units.

(10) Laundry areas

Statement of Problem and Substantiation for Public Comment

The text defining unfinished basements in 210.8(A)(5) was relocated to a new 210.2 for consistency within 210 and the NEC in general. Removing the text "storage areas, work areas, and the like" from 210.8(A)(5) and expanding the GFCI requirements in 210.8(B) to include unfinished basements identifies sufficient substantiation to define the term for the purposes of the article. This can be accomplished by locating the definition in the now available 210.2. A companion comment has been submitted to include the definition in a new 210.2.

The words "or spaces" will be added to the new definition in 210.2 for clarification. As worded in 201.8(A)(5) in First Draft, the reference to open areas in basements has been lost. This will present enforcement challenges for example; how would a habitable space within a basement that has not been finished as a "room" be treated? If the defining the term in a new 210.2 is not accepted the words "or spaces" should be added to 210.8(A)(5) so it reads; …. habitable rooms or spaces.

Public Comment No. 1436-NFPA 70-2015 [Section No. 210.8(B)]

(B) Other Than Dwelling Units.

All 125-volt, single-phase, 15- and 20-ampere receptacles installed in the locations specified in 210.8(B)(1) through (8) shall have ground-fault circuit-interrupter protection for personnel.

(3) Locations.

- Bathrooms
- Kitchens
- Rooftops

   Outdoors: Exception No. 1 to (c) and (d)

   (1) Class A Ground-Fault Circuit-Interrupter Protection (GFCI).

      (a) All single-phase receptacles rated 150 volts to ground or less, 50 amperes or less, shall have GFCI protection for personnel.

      (b) All three-phase receptacles rated 150 volts to ground or less, 100 amperes or less, shall have GFCI protection for personnel.

   (2) Classes C, D, or E Special-Purpose Ground-Fault Circuit-Interrupter Protection (SPGFCI).

      (a) All single-phase receptacles rated more than 150 volts to ground and up to 600 volts between ungrounded conductors, 100 amperes or less, shall have special-purpose ground-fault circuit-interrupter (SPGFCI) protection for personnel.

      (b) All three-phase receptacles rated more than 150 volts to ground and up to 600 volts between ungrounded conductors, 100 amperes or less, shall have special-purpose ground-fault circuit-interrupter (SPGFCI) protection for personnel.

- Bathrooms
- Kitchens
- Rooftops
- Outdoors

Exception No. 1 to (3): Receptacles on rooftops shall not be required to be readily accessible other than from the rooftop.

Exception No. 2 to (3) and (4): Receptacles that are not readily accessible and are supplied by a branch circuit dedicated to electric snow-melting, deicing, or pipeline and vessel heating equipment shall be permitted to be installed in accordance with 426.28 or 427.22, as applicable.

Exception No.

2 to (d)

4]: In industrial establishments only, where the conditions of maintenance and supervision ensure that only qualified personnel are involved, an assured equipment grounding conductor program as specified in 590.6(B)(2) shall be permitted for only those receptacle outlets used to supply equipment that would create a greater hazard if power is interrupted or having a design that is not compatible with GFCI protection.

(5) Sinks — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the sink

Exception No. 1 to (e)

5]: In industrial laboratories, receptacles used to supply equipment where removal of power would introduce a greater hazard shall be permitted to be installed without GFCI protection.

Exception No. 2 to (e)

5]: For receptacles located in patient bed locations of general care or critical care areas of health care facilities other than those covered under 210.8(B)(1), GFCI protection shall not be required.

(6) Indoor wet locations

(7) Locker rooms with associated showering facilities

(8) Garages, service bays, and similar areas other than vehicle exhibition halls and showrooms

- Crawls spaces— GFCI protection shall be provided for lighting outlets in crawl spaces at or below grade level.

- Unfinished basements — for the purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms.
IEC's position is to Delete FR 347

The code does not prohibit use of these devices and there was not enough technical substantiation to expand on GFCI protection beyond 125-volt, single phase, 15- and 20-ampere receptacles in "other than dwelling units." FR-347 is too broad. SPGCFI protection needs to be equipment specific and located in the applicable article.

(i) Crawl spaces — GFCI protection shall be provided for lighting outlets in crawl spaces at or below grade level

(j) Unfinished basements — for the purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms.

Statement of Problem and Substantiation for Public Comment

Revert to 2014 text and try again. FR 347 fails in several ways, 2 of which are: 1. Removing Exception (1) to (3) is a mistake in that now we must have a readily-accessible GFCI breaker in the panel supplying the rooftop receptacle, which if tripped while in use, necessitates a trip down from the roof, rather than simply pressing a reset button on the receptacle at hand; 2. Insufficient guidance is provided to enable the code user to select the appropriate SPGFCI Class. The vote on this FR was close and negative comments should have been heeded. This FR is not ready for prime time.

Statement of Problem and Substantiation for Public Comment

locations 1 -8 is a typo should say 210.8 (B)(3), the measurement from the sink is a companion of PC 598

Related Item

First Revision No. 347-NFPA 70-2015 [Section No. 210.8(B)]
Committee Statement

Committee Action: Rejected but see related SR

Resolution: SR-322-NFPA 70-2015

Statement:
The requirement for the Class C, D or E special purpose ground fault circuit Interrupter protection was deleted because of a concern for the improper application of this solution as well as insufficient substantiation to support expanding the requirement to these circuits.

An editorial change was made by deleting "locations" section and the sections renumbered as it was necessary due to the deletion of the items (1) and (2) of this section.

The rooftop exception was re-instated to clarify when the receptacle needs to be readily accessible.

The text regarding sinks has been revised to clarify how the measurement is made.

Patient care categories were added to correlate with Article 517 and NFPA 99.

The text regarding unfinished basements has been revised such that a definition for unfinished basements is unnecessary.

(1) Class A Ground-Fault Circuit-Interrupter Protection (GFCI).
operating at 150 volts to ground or less
-50 amperes or less, shall have GFCI protection for personnel. All three-phase receptacles rated 150 volts to ground or less, 100 and rated at 60 amperes or less

shall have
GFCI protection for personnel.

(2) Classes C, D, or E Special-Purpose Ground-Fault Circuit-Interrupter Protection (SPGFCI).

(a) All single-phase receptacles rated more than 150 volts to ground and up to 600 volts between ungrounded conductors, 100 amperes or less, shall have special-purpose ground-fault circuit-interrupter (SPGFCI) protection for personnel.

(b) All three-phase receptacles rated more than 150 volts to ground and up to 600 volts between ungrounded conductors, 100 amperes or less, shall have special-purpose ground-fault circuit-interrupter (SPGFCI) protection for personnel.

(3) Locations.
Class A Ground Fault Circuit Interrupter (GFCI) protection for personnel.

(1) Class A GFCI required locations

(a) Bathrooms (b) Kitchens (c) Rooftops

(d) Outdoors

Exception No Exception No. 1 to (c): Receptacles on rooftops shall not be required to be readily accessible other than from the rooftop.

Exception No. 2 to (c) and (d): Receptacles that are not readily accessible and are supplied by a branch circuit dedicated to electric snow-melting, deicing, or pipeline and vessel heating equipment shall be permitted to be installed in accordance with 426.28 or 427.22, as applicable.

Exception No. 2 to (d): In industrial establishments only, where the conditions of maintenance and supervision ensure that only qualified personnel are involved, an assured equipment grounding conductor program as specified in 590.6(B)(2) shall be permitted for only those receptacle outlets used to supply equipment that would create a greater hazard if power is interrupted or having a design that is not compatible with GFCI protection.

(e) Sinks — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the sink

Exception No. 1 to (e): In industrial laboratories, receptacles used to supply equipment where removal of power would introduce a greater hazard shall be permitted to be installed without GFCI protection.

Exception No. 2 to (e): For receptacles located in patient bed locations of general care or critical care areas of health care facilities other than those covered under 210.8(B) (1), GFCI protection shall not be required.

(f) Indoor wet locations (g) Locker rooms with associated showering facilities

(h) Garages, service bays, and similar areas other than vehicle exhibition halls and showrooms

(i) Crawl spaces — GFCI protection shall be provided for lighting outlets in crawl spaces at or below grade level.

(j) Unfinished basements — for the purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms.

Informational Note No.1: Three-phase GFCI protection is available for voltages up to and including 150 volts to ground. The Assured Equipment Grounding Conductor Program is sometimes used to provide personnel protection where GFCIs are not otherwise required (see 590.6(B)(2)).

Informational Note No. 2: Special Purpose Ground Fault Circuit Interrupters (SPGFCIs) are available to provide ground fault protection for receptacles rated more than 150 volts to ground and up to 600 volts between ungrounded conductors. These devices are available in both single-phase and three-phase versions, and typically have adjustable ground fault trip settings.
Statement of Problem and Substantiation for Public Comment

The added GFCI requirements for single-phase and three-phase lower voltages and also higher voltages were not substantiated by any technical data. Special Purpose GFCIs have not been proven to add any layer of safety above and beyond an "Assured Equipment Grounding Conductor Program". Introducing them to the electrical public by way of an informational note rather than a mandated requirement allows electrical professionals the opportunity to prove their worth as a valid safety device. This revision removes the requirement for SPGFCIs and also three-phase lower voltage GFCI devices, and adds them as an option in the form of informational notes.

The improper numbering of the first revision has been corrected (210.8(B)(1) through (8), which does not exist). This has been replaced by proper numbering of the locations where Class A GFCIs are required ((1)(a) through (j)).

An exception was added back from the 2014 NEC allowing receptacles on rooftops to not be readily accessible other than from the rooftop. This exception was new text in 2014 and should remain. It only makes sense to clarify what is meant by ready access on a rooftop.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-321-NFPA 70-2015 The proposed Informational notes were not included as the special purpose GFCI requirements were deleted. Increasing from 50 to 60 amperes was not accepted because there was no substantiation to do so.
Statement: Receptacles of the higher voltage and current ratings in the locations identified in 210.8(B) present the similar shock hazards as those of lower voltage and current ratings. The numbering in

the introductory paragraph was changed to correlate with the revisions to the section. Item (1)(a) and (1)(b) were incorporated into the opening paragraph.
Public Comment No. 819-NFPA 70-2015 [Section No. 210.8(B)]

(B) Other Than Dwelling Units.

All 125-volt, single-phase, 15- and 20-ampere receptacles installed in the locations specified in 210.8(B)(1) through (8) shall be permitted to have ground-fault circuit-interrupter protection for personnel.

(1) Class A Ground-Fault Circuit-Interrupter Protection (GFCI) shall be used when 210.8(B)(1)(a) or (b) apply.

(a) All single-phase receptacles rated 150 volts to ground or less, 50 amperes or less, shall be permitted to have GFCI protection for personnel.

(b) All three-phase receptacles rated 150 volts to ground or less, 100 amperes or less, shall have GFCI protection for personnel.

(2) Classes C, D, or E Special-Purpose Ground-Fault Circuit-Interrupter Protection (SPGFCI) shall be used when 210.8(B)(2)(a) or (b) apply.

(a) All single-phase receptacles rated more than 150 volts to ground and up to 600 volts between ungrounded conductors, 100 amperes or less, shall be permitted to have special-purpose ground-fault circuit-interrupter (SPGFCI) protection for personnel.

(b) All three-phase receptacles rated more than 150 volts to ground and up to 600 volts between ungrounded conductors, 100 amperes or less, shall be permitted to have special-purpose ground-fault circuit-interrupter (SPGFCI) protection for personnel.

(3) Locations.

(a) Bathrooms
(b) Kitchens
(c) Rooftops
(d) Outdoors

Exception No. 1 to (c) and (d): Receptacles that are not readily accessible and are supplied by a branch circuit dedicated to electric snow-melting, deicing, or pipeline and vessel heating equipment shall be permitted to be installed in accordance with 426.28 or 427.22, as applicable.

Exception No. 2 to (d): In industrial establishments only, where the conditions of maintenance and supervision ensure that only qualified personnel are involved, an assured equipment grounding conductor program as specified in 590.6(B)(2) shall be permitted for only those receptacle outlets used to supply equipment that would create a greater hazard if power is interrupted or having a design that is not compatible with GFCI protection.

(e) Sinks — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the sink

Exception No. 1 to (e): In industrial laboratories, receptacles used to supply equipment where removal of power would introduce a greater hazard shall be permitted to be installed without GFCI protection.

Exception No. 2 to (e): For receptacles located in patient bed locations of general care or critical care areas of health care facilities other than those covered under 210.8(B)(1), GFCI protection shall not be required.

(f) Indoor wet locations
(g) Locker rooms with associated showering facilities
(h) Garages, service bays, and similar areas other than vehicle exhibition halls and showrooms
(i) Crawls spaces — GFCI protection shall be provided for lighting outlets in crawl spaces at or below grade level.
(j) Unfinished basements — for the purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms.

Statement of Problem and Substantiation for Public Comment

The first draft of 201.8 (B) is need of a clean-up.

(i) Crawl spaces — GFCI protection shall be provided for lighting outlets in crawl spaces at or below grade level.

(j) Unfinished basements — for the purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms.

Statement of Problem and Substantiation for Public Comment

The words “125-volt, single-phase, 15- and 20-ampere” need to be deleted because the requirement now includes three-phase receptacles and receptacles rated up to 100 A.

FR 347 adds a requirement for the use of Classes C, D or E Special Purpose Ground-Fault Circuit Interrupters (SPGFCI) in specified locations where the voltage is more that 150 volts to ground. These devices are listed to UL 943C. According to UL 943C, in applications where the voltage to ground exceeds 150 volts but does not exceed 300 volts, a Class C SPGFCI is to be used. In applications where the voltage to ground exceeds 300 volts, a Class D SPGFCI may be used if an oversized equipment grounding conductor is installed. If an oversized equipment grounding conductor is not installed, a Class E SPGFCI must be used. No mention of these requirements is made in the proposed Code text, thus there is the possibility of these devices being misapplied, endangering persons who should be protected from shock. The text in (B)(2) should be deleted.

Exception No. 2 to (d)

4): In industrial establishments only, where the conditions of maintenance and supervision ensure that only qualified personnel are involved, an assured equipment grounding conductor program as specified in 590.6(B)(2), shall be permitted for only those receptacle outlets used to supply equipment that would create a greater hazard if power is interrupted or having a design that is not compatible with GFCI protection.

(5) Sinks — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the sink

Exception No. 1 to (e)

5): In industrial laboratories, receptacles used to supply equipment where removal of power would introduce a greater hazard shall be permitted to be installed without GFCI protection.

Exception No. 2 to (e): For receptacles located in patient bed locations of general care or critical care areas of health care facilities other than those covered under, 210.8(B)(1), GFCI protection shall not be required.

(6) Indoor wet locations
(7) Locker rooms with associated showering facilities
(8) Garages, service bays, and similar areas other than vehicle exhibition halls and showrooms
(9) Crawl spaces — GFCI protection shall be provided for lighting outlets in crawl spaces at or below grade level.
(10) Unfinished basements —

For the purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms.
Statement of Problem and Substantiation for Public Comment

This comment essentially returns the numbering structure of 210.8(B) to that of 2014 NEC and removes the text expanding the requirements to include single and three phase receptacles up to 600 volts and 100 amperes. There were several issues with wording of 210.8(B) in the First Draft (FR No. 347). For example; the text in the First Draft opening paragraph only references single phase, 125 volt, 15 and 20 ampere receptacles when the requirements were expanded to include receptacles to up to 600 volts, 100 amperes and three phase types, the exception numbering is not consistent and Exception No. 1 to (3), regarding rooftop GFCI receptacle devices, was removed by FR 347 but remains in the First Draft. Removing the expanded requirements solves other wording issues.

The substantiation provided for expanding the current Class A GFCI ampacity, voltage and phase requirements and to mandate special-purpose ground-fault protection circuit-interrupter, Class C, D or E (SPGFCI), protection for higher voltages as general branch circuit requirements was extremely insufficient. At these expanded levels the receptacle outlets will likely be used for specific purpose portable or other cord and plug connected equipment. Specific-purpose ground-fault protection requirements should be located in the applicable article for the equipment or the conditions such as 422 or 590 as opposed to a general branch circuit requirement in 210. Locating special purpose requirements in the appropriate article is consistent with the First Draft actions to move appliance GFCI requirements from 210 to 422.

The text defining unfinished basements in 210.8(B)(3)(j) in the First Draft was relocated to a new 210.2 for consistency within 210. Including unfinished basements in 210.8(B) and expanding the AFCI requirements in 210.12 has identified sufficient substantiation to define the term for the purposes of the article. This can be accomplished by locating the definition in the now available 210.2. A companion comment has been submitted to include the definition in a new 210.2.

Public Comment No. 425-NFPA 70-2015 [Sections 210.8(B)(1), 210.8(B)(2)]

Sections 210.8(B)(1), 210.8(B)(2)
(1) Class A Ground-Fault Circuit-Interrupter Protection (GFCI).
   (a) All single-phase receptacles rated 150 volts to ground or less, 50 amperes or less, shall have GFCI protection for personnel.
   (b) All three-phase receptacles rated 150 volts to ground or less, 100 amperes or less, shall have GFCI protection for personnel.

(2) Classes C, D, or E Special-Purpose Ground-Fault Circuit-Interrupter Protection (SPGFCI).
   (a) All single-phase receptacles rated more than 150 volts to ground and up to 600 volts between ungrounded conductors, 100 amperes or less, shall have special-purpose ground-fault circuit-interrupter (SPGFCI) protection for personnel.
   (b) All three-phase receptacles rated more than 150 volts to ground and up to 600 volts between ungrounded conductors, 100 amperes or less, shall have special-purpose ground-fault circuit-interrupter (SPGFCI) protection for personnel.

Statement of Problem and Substantiation for Public Comment

BOMA, International is requesting the committee reverse its action on mandating the use of Special Purpose GFCI's in all occupancies, where there use will have no impact in improving the safety of occupants where there is no evidence that the hazard currently exists. According to the US Bureau of Labor Statistics, a majority of the shocks (outside of residential occupancies) occur from individuals coming into contact with overhead power lines (44%) followed by workers who come into contact with wiring, transformers and other electrical components (27%) as part of their daily work routine. These statistics were reported in the ESFI report available at http://www.esfi.org/resource/electrical-safety-then-and-now-281. Currently, the code does not prohibit their use to protect personal in industrial settings and the proponent should continue to promote better engineering practices to encourage their use. BOMA agrees that improvements for electrical safety and reducing electrical shocks should be the goal, but as it was so appropriately stated in the negative comment from Mr. McGovern. “Sufficient substantiation has not been provided to expand GFCI protection beyond 125 volt receptacles in the areas specified other than the fact that new products have been developed for sale in the market place.”

Statement of Problem and Substantiation for Public Comment

The PI for "210.8(B)(2) Classes C, D, or E Special-Purpose Ground Fault Circuit-Interrupter Protection (SPGFCI)" should be DELETED.

While Class C, D, and E GFCI devices may increase safety for workers, it would be premature to mandate their usage at this time until sufficient field experience shows that they will reduce fatalities, and will not cause nuisance tripping in industrial type settings, in addition to all the 'Other Than Dwelling Units' locations that would be impacted. There is presently nothing that would prohibit installing these devices in facilities today.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-322-NFPA 70-2015
Statement: The requirement for the Class C, D or E special purpose ground fault circuit Interrupter protection was deleted because of a concern for the improper application of this solution as well as insufficient substantiation to support expanding the requirement to these circuits.

An editorial change was made by deleting "locations" section and the sections renumbered as it was necessary due to the deletion of the items (1) and (2) of this section.

The rooftop exception was re-instated to clarify when the receptacle needs to be readily accessible.

The text regarding sinks has been revised to clarify how the measurement is made.

Patient care categories were added to correlate with Article 517 and NFPA 99.

The text regarding unfinished basements has been revised such that a definition for unfinished basements is unnecessary.
Public Comment No. 1023-NFPA 70-2015 [Section No. 210.8(B)(3)]

(3) Locations.

(a) Bathrooms (b) Kitchens (c) Rooftops
(d) Outdoors

Exception No. 1 to (c) and (d): Receptacles that are not readily accessible and are supplied by a branch circuit dedicated to electric snow-melting, deicing, or pipeline and vessel heating equipment shall be permitted to be installed in accordance with 426.28 or 427.22, as applicable.

Exception No. 2 to (d): In industrial establishments only, where the conditions of maintenance and supervision ensure that only qualified personnel are involved, an assured equipment grounding conductor program as specified in 590.6(B)(2) shall be permitted for only those receptacle outlets used to supply equipment that would create a greater hazard if power is interrupted or having a design that is not compatible with GFCI protection.

Exception No. 3 to (d): For receptacles in outdoor locations in Articles 520, 525 and 530 occupancies GFCI and SPGFCI protection shall be permitted but not required.

(e) Sinks — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the sink

Exception No. 1 to (e): In industrial laboratories, receptacles used to supply equipment where removal of power would introduce a greater hazard shall be permitted to be installed without GFCI protection.

Exception No. 2 to (e): For receptacles located in patient bed locations of general care or critical care areas of health care facilities other than those covered under 210.8(B) (1), GFCI protection shall not be required.

(f) Indoor wet locations (g) Locker rooms with associated showering facilities

(h) Garages, service bays, and similar areas other than vehicle exhibition halls and showrooms

(i) Crawl spaces — GFCI protection shall be provided for lighting outlets in crawl spaces at or below grade level.

(j) Unfinished basements — for the purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms.

Statement of Problem and Substantiation for Public Comment

In many cases GFCI and SPGFCI protection is not reliably functional in these supervised occupancies with the equipment involved. In a previous cycle a similar proposal was made. UL determined that the equipment had not been evaluated for this use and would have to be considered on a case by case basis. There are applications where this equipment can be applied and applications where it doesn’t function properly. This is partially due to very long runs of sets of single-conductor cables, phase-cut single-phase dimming controls on three-phase circuits, arc lamp ballasts with high harmonic content, and portable generators bonded only to their frame. The proposed Exception allows the use of this equipment where it can be applied and does not require its use where it does not function properly. The last time a similar proposal was made proposals in Articles 520, 525 and 530 were made to negate the requirements. When the proposal was withdrawn the counter proposals in Article 520 and 530 were withdrawn and the requirements in Section 525.23 were revised to coordinate with the requirements of 210. If Exception 3 is not granted, Section 525.23 will need to be revised to re-coordinate with 210 and similar sections re-inserted into Article 520 and 530.

Entertainment electrical equipment is mostly portable moving from show to show. Each time it is moved it becomes a new installation involving a new electrical permit and a new inspection. Large stocks of rental electrical equipment that is compliant one day is un-rentable the next day if the requirements change. The requirements for GFCI’s, as stated in the NEC, appear to be frequency neutral. Consequently it applies to all the ungrounded DC systems found in Article 530. The UL standard for GFCI’s indicates that they are for use on AC circuits.

Statement of Problem and Substantiation for Public Comment

This Public Comment is responsive to NEC® Correlating Committee Note CN155 regarding 2017 NEC® First Revision FR4247 for Article 517 [and First Revision FR347 for Section 210.8(B)].

In accordance with 4.3.3 of the National Electrical Code® Style Manual and 2.3.2.11 of the Manual of Style for NFPA Technical Committee Documents regarding extracted materials, NFPA 99 Fundamentals Technical Committee, as the committee responsible for the source document, HAS CONSENTED to use parenthetic references between specific older and current NFPA 99 terminology during a transition to current NFPA 99 terminology in the National Electrical Code®.

Please see the attached PDF file for details and for the requested action.

(f) Indoor wet locations
(g) Locker rooms with associated showering facilities

(h) Garages, service bays, and similar areas other than vehicle exhibition halls and showrooms

(i) Crawl spaces — GFCI protection shall be provided for lighting outlets in crawl spaces at or below grade level.

(j) Unfinished basements — for the purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms.

(C) Boat Hoists.

GFCI protection shall be provided for outlets not exceeding 240 volts that supply boat hoists installed in dwelling unit locations.

(D) Kitchen Dishwasher Branch Circuit.

GFCI protection shall be provided for outlets that supply dishwashers installed in dwelling unit locations.

---

### Statement of Problem and Substantiation for Public Comment

IEC’s position is to reject FR-348 and FR-349.

GFCI protection for boat hoists and dishwashers needs to remain in the branch circuit or outlet. The proposed text in FR-4801 (422.5) allows the option of providing GFCI protection for boat hoists and dishwashers in the attachment plug, the supply cord or installed within the appliance. There is no UL standard that requires GFCI protection integral with appliances or their cords. Moving this requirement to Article 422, providing the option for appliances equipped with GFCI protection to meet this requirement, would reduce the existing protection afforded by the NEC. For new construction, GFCI protection afforded in the outlet or in the circuit breaker is the best solution for safety as this solution pays no regards to whether or not GFCI protection is provided for in the cord of the appliance.

Public Comment No. 267-NFPA 70-2015 [Section No. 210.11(C)(4)]

(4) Garage Branch Circuits.
In addition to the number of branch circuits required by other parts of this section, at least one 20-ampere branch circuit shall be provided to supply receptacle outlet(s) in attached garages and in detached garages with electric power.

Statement of Problem and Substantiation for Public Comment

The first draft wording requires that electric power be provided to a detached garage at a dwelling unit. The decision to provide electric power to a detached garage is a design issue and not a code issue. Electric power to a detached garage is not required by the 2014 NEC. There is nothing in the substantiation for the PI that suggests a need for this new requirement to provide electric power to a detached garage.

Committee Statement
Committee Action: Rejected
Resolution: The First Revision wording does not require that electric power be provided to a detached garage at a dwelling unit.
Public Comment No. 952-NFPA 70-2015 [Section No. 210.11(C)(4)]

(4) Garage Branch Circuits.
In addition to the number of branch circuits required by other parts of this section, at least one 20-ampere branch circuit shall be provided to supply garage receptacle outlet(s) required by 210.52(G)(1) and other outlets and devices in that particular garage. Such circuit(s) shall have no other outlets.
Exception: This branch circuit shall be permitted to supply a receptacle outlet(s) located immediately adjacent on the outside of the garage.

Statement of Problem and Substantiation for Public Comment

As originally proposed by PI 1010, this proposed language is similar in structure to the existing text at 210.11(C). This proposed text (added by this comment) is also being proposed at 210.52(G)(1). Section 210.52 is requirements for dwelling unit receptacle outlets. A more appropriate location for this text that deals with the branch circuit supplying these receptacle outlets is 210.11(C), which deals with required branch circuits for dwelling units.

This proposed text and the proposed exception will allow the garage lighting outlet(s) and related switches, along with an outdoor receptacle outlet(s) located on the outside of the garage to also be supplied from the garage branch circuit without the installer having to install a separate branch circuit to supply these lighting outlets and outside receptacle outlet as currently required by the 2014 NEC text at 210.52(G)(1).

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-324-NFPA 70-2015
Statement: Changes were made to clarify that readily accessible outdoor receptacle outlets are to be permitted on the garage branch circuit. These additional outlets provide convenience receptacles similar to those used in the garage.
210.12 Arc-Fault Circuit-Interrupter Protection.

Arc-fault circuit-interrupter protection shall be provided as required in 210.12(A), (B), and (C). The arc-fault circuit interrupter shall be installed in a readily accessible location.

(A) Dwelling Dormitory Units.

All 120-volt, single-phase, 15- and 20-ampere branch circuits supplying outlets or devices installed in dwelling units in dormitory units shall be protected by any of the means described in 210.12(A)(1) through (6):

(1) A listed combination-type arc-fault circuit interrupter, installed to provide protection of the entire branch circuit.

(2) A listed branch/feeder-type AFCI installed at the origin of the branch circuit in combination with a listed outlet branch-circuit-type arc-fault circuit interrupter installed at the first outlet box on the branch circuit. The first outlet box in the branch circuit shall be marked to indicate that it is the first outlet of the circuit.

(3) A listed supplemental arc protection circuit breaker installed at the origin of the branch circuit in combination with a listed outlet branch-circuit-type arc-fault circuit interrupter installed at the first outlet box on the branch circuit where all of the following conditions are met:

(4) The branch-circuit wiring shall be continuous from the branch-circuit overcurrent device to the outlet branch-circuit arc-fault circuit interrupter.

(5) The maximum length of the branch-circuit wiring from the branch-circuit overcurrent device to the first outlet shall not exceed 15.2 m (50 ft) for a 14 AWG conductor or 21.3 m (70 ft) for a 12 AWG conductor.

(6) The first outlet box in the branch circuit shall be marked to indicate that it is the first outlet of the circuit.

(7) A listed outlet branch-circuit-type arc-fault circuit interrupter installed at the first outlet on the branch circuit in combination with a listed branch-circuit overcurrent protective device where all of the following conditions are met:

(8) The branch-circuit wiring shall be continuous from the branch-circuit overcurrent device to the outlet branch-circuit arc-fault circuit interrupter.

(9) The maximum length of the branch-circuit wiring from the branch-circuit overcurrent device to the first outlet shall not exceed 15.2 m (50 ft) for a 14 AWG conductor or 21.3 m (70 ft) for a 12 AWG conductor.

(10) The first outlet box in the branch circuit shall be marked to indicate that it is the first outlet of the circuit.

(11) If RMC, IMC, EMT, Type MC, or steel-armored Type AC cables meeting the requirements of 250.118, metal wireways, metal auxiliary gutters, and metal outlet and junction boxes are installed for the portion of the branch circuit between the branch-circuit overcurrent device and the first outlet, it shall be permitted to install a listed outlet branch-circuit-type AFCI at the first outlet to provide protection for the remaining portion of the branch circuit.

(12) Where a listed conduit or tubing or Type MC cable is encased in not less than 50 mm (2 in.) of concrete for the portion of the branch circuit between the branch-circuit overcurrent device and the first outlet, it shall be permitted to install a listed outlet branch-circuit-type AFCI at the first outlet to provide protection for the remaining portion of the branch circuit.

Exception: Where an individual branch circuit to a fire alarm system installed in accordance with 760.41(B) or 760.121(B) is installed in RMC, IMC, EMT, or metal wireways or auxiliary gutters or steel-sheathed cable, Type AC or Type MC, meeting the requirements of 250.118, with metal outlet and junction boxes, AFCI protection shall be permitted to be omitted.

Informational Note No. 1: For information on combination-type and branch/feeder-type arc-fault circuit interrupters, see UL 1699-2011, Standard for Arc-Fault Circuit Interrupters. For information on outlet branch-circuit type arc-fault circuit interrupters, see UL Subject 1699A, Outline of Investigation for Outlet Branch Circuit Arc-Fault Circuit-Interrupters. For information on system combination AFCIs, see UL Subject 1699C, Outline of Investigation for System Combination Arc-Fault Circuit Interrupters.

Informational Note No. 2: See 29.6.3(5) of NFPA 72-2013, National Fire Alarm and Signaling Code, for information related to secondary power-supply requirements for smoke alarms installed in dwelling units.

Informational Note No. 3: See 760.41(B) and 760.121(B) for power-supply requirements for fire alarm systems.
Dormitory Units.

All 120-volt, single-phase, 15- and 20-ampere branch circuits supplying outlets and devices installed in dormitory unit bedrooms, living rooms, hallways, closets, bathrooms, and similar rooms shall be protected by a listed arc-fault circuit interrupter meeting the requirements of 210.12(A)(1) through (6) as appropriate.

Branch Circuit Extensions or Modifications — Dwelling Units and Dormitory Units.

In any of the areas specified in 210.12(A) or 210.12(C), where branch-circuit wiring is modified, replaced, or extended, the branch circuit shall be protected by one of the following:

1. A listed combination-type AFCI located at the origin of the branch circuit
2. A listed outlet branch-circuit type-AFCI located at the first receptacle outlet of the existing branch circuit

Exception: AFCI protection shall not be required where the extension of the existing conductors is not more than 1.8 m (6 ft) and does not include any additional outlets or devices.

Guest Rooms and Guest Suites.

All 120-volt, single-phase, 15- and 20-ampere branch circuits supplying outlets and devices installed in guest rooms and guest suites of hotels and motels shall be protected by a listed arc-fault circuit interrupter meeting the requirements of 210.12(A)(1) through (6) as appropriate.

Statement of Problem and Substantiation for Public Comment

The current afci breakers on the market are prone to tripping for reasons not related to arcs or anything remotely dangerous. On every electrical contractor forum in every supply house and talking to countless EC's there are talks of contractors having to "chase ghosts", breakers tripping at random and not on demand (cant replicate trip). Many of these contractors, me included have spent countless dollars trying to find what is causing these trips. The findings of these Licensed Electrical Contractors in the field dealing with these breakers every day are that they ghost trip at random due to things such as ie: LED bulbs, electronic equipment of all kinds including but not limited to dvd players, TV's, computers etc, electronic noise, line side connections (power company conns) dimmers, electronic switching devices, vacuums, hair dryers, power tools, fluorescent light ballasts and even ham radios in the neighborhood. Nothing is wrong with any of this equipment it is just interfering with the electronics of the afcis. I have personally also had homeowners refrigerators tripping afci when it cycled into energy saving mode causing hundreds of dollars of spoiled food each time. I agree that the idea of afci technology is relevant but the current variation on the market is defective costing electrical contractors countless dollars trying to troubleshoot a circuit where there is nothing wrong. These devices should not be required in dwellings until such a time that these nuisance ghost trip issues can be resolved. By not doing so you are costing the very people (electrical contractors) who support and for who this code is written enough money to put us out of business. Contractors cannot bear this cost. Why do we have to bear the responsibility, cost and loss of respect and customers due to something which is obviously a manufacturer defect. If you doubt what I say please use your database of electrical contractors and do a poll of how many of these nuisance trips each are having, this is a serious enough issue. There are polls out there already which show over 80% of trade professional respondents who want to eliminate 210-12 altogether(mikeholt.com) I have yet to hear from a contractor who has not wasted thousands of dollars chasing these non existent afci ghosts. PLEASE TAKE THIS ISSUE SERIOUSLY, as I know the manufactures will deny any problems. Just because a product is mass produced does not mean that it has to be forced to market and definitely not forced into code until that product is 100% effective and free of nuisance issues which have proven to cost contractors countless dollars. It will also set off a firestorm when millions of homeowners lose there refrigerator and freezer contents because of a defective breaker. By leaving dormitories and guest rooms manufacturers still have places which are not permanent residences to BETA test and work out these issues. Another option is removing 210-12 altogether until afci technology is 100%. I personally think afci technology should be removed from premises wiring and integrated into all manufactured plug in or hard wired EQUIPMENT. This would eliminate all false circuit trips and would be a simple to troubleshoot problem as only faulty equipment would trip, not entire circuit.

Committee Statement

Committee Action: Rejected
Resolution: The need for arc fault protection in dwelling units is well substantiated. No mention was made in the substantiation of contractors contacting AFCI manufacturers for assistance which is an important step in the problem resolution process.
Public Comment No. 439-NFPA 70-2015 [ Section No. 210.12(A) ]

(A) Dwelling Units.

All 120-volt, single-phase, 15- and 20-ampere branch circuits supplying outlets or devices installed in dwelling units shall be protected by any of the means described in 210.12(A)(1) through (6):

1. A listed combination-type arc-fault circuit interrupter, installed to provide protection of the entire branch circuit.

2. A listed branch/feeder-type AFCI installed at the origin of the branch circuit in combination with a listed outlet branch-circuit-type arc-fault circuit interrupter installed at the first outlet box on the branch circuit. The first outlet box in the branch circuit shall be marked to indicate that it is the first outlet of the circuit.

3. A listed supplemental arc protection circuit breaker installed at the origin of the branch circuit in combination with a listed outlet branch-circuit-type arc-fault circuit interrupter installed at the first outlet box on the branch circuit where all of the following conditions are met:
   4. The branch-circuit wiring shall be continuous from the branch-circuit overcurrent device to the outlet branch-circuit arc-fault circuit interrupter.
   5. The maximum length of the branch-circuit wiring from the branch-circuit overcurrent device to the first outlet shall not exceed 15.2 m (50 ft) for a 14 AWG conductor or 21.3 m (70 ft) for a 12 AWG conductor.
   6. The first outlet box in the branch circuit shall be marked to indicate that it is the first outlet of the circuit.

7. A listed outlet branch-circuit-type arc-fault circuit interrupter installed at the first outlet on the branch circuit in combination with a listed branch-circuit overcurrent protective device where all of the following conditions are met:
   8. The branch-circuit wiring shall be continuous from the branch-circuit overcurrent device to the outlet branch-circuit arc-fault circuit interrupter.
   9. The maximum length of the branch-circuit wiring from the branch-circuit overcurrent device to the first outlet shall not exceed 15.2 m (50 ft) for a 14 AWG conductor or 21.3 m (70 ft) for a 12 AWG conductor.
   10. The first outlet box in the branch circuit shall be marked to indicate that it is the first outlet of the circuit.
   11. The combination of the branch-circuit overcurrent device and outlet branch-circuit AFCI shall be identified as meeting the requirements for a system combination–type AFCI and shall be listed as such.

12. If RMC, IMC, EMT, Type MC, or steel-armored Type AC cables meeting the requirements of 250.118, metal wireways, metal auxiliary gutters, and metal outlet and junction boxes are installed for the portion of the branch circuit between the branch-circuit overcurrent device and the first outlet, it shall be permitted to install a listed outlet branch-circuit-type AFCI at the first outlet to provide protection for the remaining portion of the branch circuit.

13. Where a listed conduit or tubing or Type MC cable is encased in not less than 50 mm (2 in.) of concrete for the portion of the branch circuit between the branch-circuit overcurrent device and the first outlet, it shall be permitted to install a listed outlet branch-circuit-type AFCI at the first outlet to provide protection for the remaining portion of the branch circuit.

**Exception:** Where an individual branch circuit to a fire alarm system installed in accordance with 760.41(B) or 760.121(B) is installed in RMC, IMC, EMT, or metal wireways or auxiliary gutters or steel-sheathed cable, Type AC or Type MC, meeting the requirements of 250.118, with metal outlet and junction boxes, AFCI protection shall be permitted to be omitted.

Informational Note No. 1: For information on combination-type and branch/feeder-type arc-fault circuit interrupters, see UL 1699-2011, Standard for Arc-Fault Circuit Interrupters. For information on outlet branch-circuit type arc-fault circuit interrupters, see UL Subject 1699A, Outline of Investigation for Outlet Branch Circuit Arc-Fault Circuit-Interrupters. For information on system combination AFCIs, see UL Subject 1699C, Outline of Investigation for System Combination Arc-Fault Circuit Interrupters.

Informational Note No. 2: See 29.6.3(5) of NFPA 72-2013, National Fire Alarm and Signaling Code, for information related to secondary power-supply requirements for smoke alarms installed in dwelling units.

Informational Note No. 3: See 760.41(B) and 760.121(B) for power-supply requirements for fire alarm systems.

Statement of Problem and Substantiation for Public Comment

The Committee Statement of FR329 which supported the elimination of 210.12 (A) (4) used excerpts from the UL research report titled “Effectiveness of Circuit Breakers in Mitigating Parallel Arcing Faults in the HomeRun”. It should be noted that this was updated by a later report titled “Evaluation of Run Length and Available Current on Breaker Ability to Mitigate Parallel Arcing Faults – Part II: Effect of run Length with 500A Available at the Panelboard”. The following statement is extracted from its summary on pages 3-4.

“The initial study on this topic attempted to evaluate the magnetic trip level of residential 15- and 20-amp circuit breakers to determine whether a generalized magnetic trip distribution could be found. The initial set of circuit breakers, which were sampled from four North...
American manufacturers and included circuit breakers of different designs for each manufacturer, suggested that 99% of all circuit breakers would magnetically trip at or below 300A for 15A breakers and 350A for 20A breakers. However, follow-up testing one year later negated this findings, with circuit breakers of the same model number but of a different batch had significantly different magnetic trip levels, varying by 50A or more for some manufacturers, yet varying for others. These results showed that magnetic trip levels could conceivably be controlled, but were not in all cases. The revised data showed that panelboard current and run length would need to be set assuming magnetic trip thresholds as high as 400-450A would be needed, which makes arc mitigating using magnetic trip levels not specifically calibrated for this application impractical as well as potentially unreliable. Therefore, the results of Part I of this work showed that circuit breakers with magnetic trip levels calibrated for the purpose of mitigating parallel arcing faults would be necessary."

This updated UL report clearly indicates that further investigation confirms that ordinary residential breakers used for arc mitigation are “impractical” and “potentially unreliable” from an arc fault protection perspective.

Additionally, many members of CMP 2 have witnessed testing which demonstrates that ordinary thermal magnetic circuit breakers will NOT provide arcing protection. This clearly refutes the misleading conclusions which some have drawn from previously submitted reports.

There is no technical reason to reduce the level of safety provided by the other five options by deleting the requirement for a listed system combination AFCI in option 4. Standard thermal magnetic circuit breakers are not designed, tested or listed to detect and interrupt low level arcing faults. The American Circuit Breaker Manufacturers Association (whose members consist of Eaton, General Electric, Schneider Electric and Siemens) does not support the claims that the magnetic trip characteristics will protect the home run circuit from parallel arcing faults.

The American Circuit Breaker Manufacturers Association (ACBMA) recommends that NFPA breakout the proposed deletion of 210.12(A)(4)(d) as a ballotable detail.

Committee Statement
Committee Action: Rejected
Resolution: During the First Draft stage 210.12(A)(4)(d) was removed since no product standard exists for a system combination AFCI. There is no listed system combination AFCI. Restating several reasons for continuing the action of removing 210.12(A)(4)(d): 1 - Acceptable alternative products meeting the listing requirements for an outlet branch-circuit AFCI (receptacle) and meeting the installation requirements of 210.12(A)(4) a, b and c continues to be encouraged. Listed OBC AFCIs are available in the marketplace that would meet the Code as written in the First Revision. 2 - As mentioned in the panel statement for the First Revision, the UL report “Influence of Damage and Degradation on Breakdown Voltage of NM Cables” clearly explains that parallel arcing on the “home run” portion of the branch circuit is unlikely to ignite the cable insulation or nearby combustibles under the conditions by which the samples were tested. Further, this report also categorizes the time that a parallel arc exists (in the home run) which is too short to ignite combustibles due to insufficient energy transfer. Additionally, the report informs that this short time duration is far shorter than the maximum time (8 half cycles) a listed AFCI is required to interrupt an parallel arcing fault which infrers that a listed AFCI at the service panel is not required to interrupt arcs of this short duration (1.4 of a cycle). Parallel arcing does not continue for the allowable maximum of 8 half cycles. 3 - The Panel is aware that this is a reduction in parallel arc protection in the “home run” and considers the trade off in protection, for the sake of making alternative protection devices available in the marketplace acceptable. As with other Code-required products, acceptable alternatives promote competition and new product development.
Dwelling Units.

All 120-volt, single-phase, 15- and 20-ampere branch circuits supplying outlets or devices installed in dwelling units shall be protected by any of the means described in 210.12(A)(1) through (6):

1. A listed combination-type arc-fault circuit interrupter, installed to provide protection of the entire branch circuit.

2. A listed branch/feeder-type AFCI installed at the origin of the branch circuit in combination with a listed outlet branch-circuit-type arc-fault circuit interrupter installed at the first outlet box on the branch circuit. The first outlet box in the branch circuit shall be marked to indicate that it is the first outlet of the circuit.

3. A listed supplemental arc protection circuit breaker installed at the origin of the branch circuit in combination with a listed outlet branch-circuit-type arc-fault circuit interrupter installed at the first outlet box on the branch circuit where all of the following conditions are met:

   4. The branch-circuit wiring shall be continuous from the branch-circuit overcurrent device to the outlet branch-circuit arc-fault circuit interrupter.

   5. The maximum length of the branch-circuit wiring from the branch-circuit overcurrent device to the first outlet shall not exceed 15.2 m (50 ft) for a 14 AWG conductor or 21.3 m (70 ft) for a 12 AWG conductor.

   6. The first outlet box in the branch circuit shall be marked to indicate that it is the first outlet of the circuit.

7. A listed outlet branch-circuit-type arc-fault circuit interrupter installed at the first outlet on the branch circuit in combination with a listed branch-circuit overcurrent protective device where all of the following conditions are met:

   8. The branch-circuit wiring shall be continuous from the branch-circuit overcurrent device to the outlet branch-circuit arc-fault circuit interrupter.

   9. The maximum length of the branch-circuit wiring from the branch-circuit overcurrent device to the first outlet shall not exceed 15.2 m (50 ft) for a 14 AWG conductor or 21.3 m (70 ft) for a 12 AWG conductor.

   10. The first outlet box in the branch circuit shall be marked to indicate that it is the first outlet of the circuit.

11. If RMC, IMC, EMT, Type MC, or steel-armored Type AC cables meeting the requirements of 250.118, metal wireways, metal auxiliary gutters, and metal outlet and junction boxes are installed for the portion of the branch circuit between the branch-circuit overcurrent device and the first outlet, it shall be permitted to install a listed outlet branch-circuit-type AFCI at the first outlet to provide protection for the remaining portion of the branch circuit.

12. Where a listed conduit or tubing or Type MC cable is encased in not less than 50 mm (2 in.) of concrete for the portion of the branch circuit between the branch-circuit overcurrent device and the first outlet, it shall be permitted to install a listed outlet branch-circuit-type AFCI at the first outlet to provide protection for the remaining portion of the branch circuit.

Exception:

Where AFCI protection shall not be required for an individual branch circuit to supplying a fire alarm system, installed in accordance with 760.41(B) or 760.121(B) is installed in RMC, IMC, EMT, or metal wireways or auxiliary gutters or steel-sheathed a metallic raceway, metallic auxiliary gutter, steel-armored cable, Type AC, MC or Type MC, AC systems, meeting the requirements of 250.118, with metal outlet and junction boxes, AFCI protection shall be permitted to be omitted metallic boxes, conduit bodies, and enclosures.

Informational Note No. 1: For information on combination-type and branch/feeder-type arc-fault circuit interrupters, see UL 1699-2011, Standard for Arc-Fault Circuit Interrupters. For information on outlet branch-circuit type arc-fault circuit interrupters, see UL Subject 1699A, Outline of Investigation for Outlet Branch Circuit Arc-Fault Circuit-Interrupters. For information on system combination AFCIs, see UL Subject 1699C, Outline of Investigation for System Combination Arc-Fault Circuit Interrupters.

Informational Note No. 2: See 29.6.3(5) of NFPA 72-2013, National Fire Alarm and Signaling Code, for information related to secondary power-supply requirements for smoke alarms installed in dwelling units.

Informational Note No. 3: See 760.41(B) and 760.121(B) for power-supply requirements for fire alarm systems.
The only thing not allowed is LTFMC and FMC both are made with steel and have the same strength as the armored cable and should be allowed. It would be valuable to have some flexibility in the field for an outdoor or indoor installations. You would only need to reference a metallic raceway and eliminate the laundry list. Metal outlet boxes and junction boxes is to narrow of an allowance, a more general statement covering most installation would be Metal boxes, conduit fittings and enclosures. The current language is confusing, “permitted to be omitted” and appears at the end of the paragraph. Say what this is for (no AFCI) and the give the requirements (Steel everything).

Statement of Problem and Substantiation for Public Comment

Revision only adds new item (4)(d). Remaining text is existing.
There is no technical reason to reduce the level of safety afforded by the listed solutions in the other five installation options by deleting the requirement for a listed system combination AFCI in option 4. There is a need to verify that the circuit breaker and OBC AFCI can together provide arc fault protection for the entire branch circuit. NEMA proposed the existing text in 210.12(A)(4) as part of ROC-2-44 in the 2014 revision cycle. Standard thermal-magnetic circuit breakers are not designed, tested or listed to detect and interrupt low level arcing faults. There is no NEMA circuit breaker manufacturer that supports these claims being made about their products.

Committee Statement
Committee Action: Rejected
Resolution: During the First Draft stage 210.12(A)(4)(d) was removed since no product standard exists for a system combination AFCI. There is no listed system combination AFCI. Restating several reasons for continuing the action of removing 210.12(A)(4)(d); 1 - Acceptable alternative products meeting the listing requirements for an outlet branch-circuit AFCI (receptacle) and meeting the installation requirements of 210.12(A)(4) a, b and c continues to be encouraged. Listed OBC AFCIs are available in the marketplace that would meet the Code as written in the First Revision. 2 - As mentioned in the panel statement for the First Revision, the UL report “Influence of Damage and Degradation on Breakdown Voltage of NM Cables” clearly explains that parallel arcing on the “home run” portion of the branch circuit is unlikely to ignite the cable insulation or nearby combustibles under the conditions by which the samples were tested. Further, this report also categorizes the time that a parallel arc exists (in the home run) which is too short to ignite combustibles due to insufficient energy transfer. Additionally, the report informs that this short time duration is far shorter than the maximum time (8 half cycles) a listed AFCI is required to interrupt an parallel arcing fault which infers that a listed AFCI at the service panel is not required to interrupt arcs of this short duration (1.4 of a cycle). Parallel arcing does not continue for the allowable maximum of 8 half cycles. 3 - The Panel is aware that this is a reduction in parallel arc protection in the “home run” and considers the trade off in protection, for the sake of making alternative protection devices available in the marketplace acceptable. As with other Code-required products, acceptable alternatives promote competition and new product development.
Public Comment No. 855-NFPA 70-2015 [Section No. 210.12(A)]

(A) Dwelling Units.

All 120-volt, single-phase, 15- and 20-ampere branch circuits supplying outlets or devices installed in dwelling units shall be protected by any of the means described in 210.12(A)(1) through (6):

1. A listed combination-type arc-fault circuit interrupter, installed to provide protection of the entire branch circuit.

2. A listed branch-feeder-type AFCI installed at the origin of the branch circuit in combination with a listed outlet branch-circuit-type arc-fault circuit interrupter installed at the first outlet box on the branch circuit. The first outlet box in the branch circuit shall be marked to indicate that it is the first outlet of the circuit.

3. A listed supplemental arc protection circuit breaker installed at the origin of the branch circuit in combination with a listed outlet branch-circuit-type arc-fault circuit interrupter installed at the first outlet box on the branch circuit where all of the following conditions are met:
   - The branch-circuit wiring shall be continuous from the branch-circuit overcurrent device to the outlet branch-circuit arc-fault circuit interrupter.
   - The maximum length of the branch-circuit wiring from the branch-circuit overcurrent device to the first outlet shall not exceed 15.2 m (50 ft) for a 14 AWG conductor or 21.3 m (70 ft) for a 12 AWG conductor.
   - The first outlet box in the branch circuit shall be marked to indicate that it is the first outlet of the circuit.

4. A listed outlet branch-circuit-type arc-fault circuit interrupter installed at the first outlet on the branch circuit in combination with a listed branch-circuit overcurrent protective device where all of the following conditions are met:
   - The branch-circuit wiring shall be continuous from the branch-circuit overcurrent device to the outlet branch-circuit arc-fault circuit interrupter.
   - The maximum length of the branch-circuit wiring from the branch-circuit overcurrent device to the first outlet shall not exceed 15.2 m (50 ft) for a 14 AWG conductor or 21.3 m (70 ft) for a 12 AWG conductor.
   - The first outlet box in the branch circuit shall be marked to indicate that it is the first outlet of the circuit.

5. The combination of the branch-circuit overcurrent device and outlet branch-circuit AFCI shall be identified as meeting the requirements of NFPA 70 at the time the installation is made.

Exception: Where an individual branch circuit to a fire alarm system installed in accordance with 760.41(B) or 760.121(B) is installed in RMC, IMC, EMT, Type MC, or steel-armored Type AC cables meeting the requirements of 250.118, metal wireways, metal auxiliary gutters, and metal outlet and junction boxes are installed for the portion of the branch circuit between the branch-circuit overcurrent device and the first outlet, it shall be permitted to install a listed outlet branch-circuit-type AFCI at the first outlet to provide protection for the remaining portion of the branch circuit.

Where a listed conduit or tubing or Type MC cable is encased in not less than 50 mm (2 in.) of concrete for the portion of the branch circuit between the branch-circuit overcurrent device and the first outlet, it shall be permitted to install a listed outlet branch-circuit-type AFCI at the first outlet to provide protection for the remaining portion of the branch circuit.

Informational Note No. 1: For information on combination-type and branch-feeder-type arc-fault circuit interrupters, see UL 1699, Standard for Arc-Fault Circuit Interrupters. For information on outlet branch-circuit type arc-fault circuit interrupters, see UL Subject 1699A, Outline of Investigation for Outlet Branch Circuit Arc-Fault Circuit-Interrupters. For information on system combination AFCIs, see UL Subject 1699C, Outline of Investigation for System Combination Arc-Fault Circuit Interrupters.

Informational Note No. 2: See 39.6.3(5) of NFPA 72-2013, National Fire Alarm and Signaling Code, for information related to secondary power-supply requirements for smoke alarms installed in dwelling units.

Informational Note No. 3: See 760.41(B) and 760.121(B) for power-supply requirements for fire alarm systems.

Statement of Problem and Substantiation for Public Comment

The deletion of 210.12(A)(4)(d) is not acceptable due to the reduction in safety created by eliminating the listing requirement. The listing requirement for demonstrating arc fault protection of the entire branch circuit and the cords connected to it is currently found in all four permitted protection methods. In order to remove a listing requirement from any of the four protection methods and not reduce or compromise safety, you must be convinced the protection method will operate within the UL 1699 parameters without any verification.

The acceptance of this FR ignores the Panel’s acceptance of Comment 2-52 that was introduced by UL and others during the development of the 2014 NEC. The Panel statement cites the UL research report titled, “Effectiveness of Circuit Breakers in Mitigating
Parallel Arcing Faults in the Home Run" as providing significant statistical assurance that the "home run" portion of the branch circuit will be protected from parallel arcing faults by standard circuit breakers. This report was revised three months after it was issued, as documented in UL Comment 2-52, and then followed up by two additional reports based on further research. The second report, "Evaluation of Run Length and Available Current on Breaker Ability to Mitigate Parallel Arcing Faults - Part I: Effect of Panelboard Current for 50 Foot Run Lengths" refutes critical findings in the first report, which includes the following:

a) "Evaluation of the magnetic trip level of circuit breakers…show that breaker magnetic trip levels are not sufficiently reliable and consistent to allow for a generalized assumption of an upper bound, as was proposed before", and

b) "…more controlled verification of the magnetic trip level of a circuit breaker intended for mitigating parallel arcing faults may be needed", and

c) "…the magnetic trip level of circuit breakers is not as well controlled as was previously found in a previous study.", and

d) "Circuit breakers with magnetic trip levels 200A or greater failed to mitigate a large fraction of the arcing events in eight half-cycles."

All of the UL research reports on this topic must be considered, unfortunately the only one cited in the PI and the Panel statement was the initial unrevised UL report. It is important for the public record to reflect accurate information for Panel consideration and comment. The Panel statement also cites the UL research report titled “Influence of Damage and Degradation on Breakdown Voltage of NM Cables”, however, the conclusion cited in the Committee statement focuses on only two important but very narrow damage events; voltage surges and hammer damage. There are many other ways and documented occurrences about how NM cable can be damaged.

Since the submission of UL Comment 2-52 test data has been presented to the UL 1699 Standards Technical Panel showing that standard thermal-magnetic circuit breakers cannot pass the UL 1699 performance requirements relating to branch circuit arc fault protection, leaving a protection gap for the home run of the branch circuit. No data has been presented to justify removing the listing requirement in 210.12(A)(4). Standard thermal-magnetic circuit breakers are not designed and tested to detect and interrupt low level arcing faults. No manufacturer claims that they can, which is why AFCI protection was identified as a need to provide such protection.

Committee Statement
Committee Action: Rejected
Resolution: During the First Draft stage 210.12(A)(4)(d) was removed since no product standard exists for a system combination AFCI. There is no listed system combination AFCI. Restating several reasons for continuing the action of removing 210.12(A)(4)(d): 1 - Acceptable alternative products meeting the listing requirements for an outlet branch-circuit AFCI (receptacle) and meeting the installation requirements of 210.12(A)(4) a, b and c continues to be encouraged. Listed OBC AFCIs are available in the marketplace that would meet the Code as written in the First Revision. 2 - As mentioned in the panel statement for the First Revision, the UL report “Influence of Damage and Degradation on Breakdown Voltage of NM Cables” clearly explains that parallel arcing on the "home run" portion of the branch circuit is unlikely to ignite the cable insulation or nearby combustibles under the conditions by which the samples were tested. Further, this report also categorizes the time that a parallel arc exists (in the home run) which is too short to ignite combustibles due to insufficient energy transfer. Additionally, the report informs that this short time duration is far shorter than the maximum time (8 half cycles) a listed AFCI is required to interrupt an parallel arcing fault which infers that a listed AFCI at the service panel is not required to interrupt arcs of this short duration (1.4 of a cycle). Parallel arcing does not continue for the allowable maximum of 8 half cycles. 3 - The Panel is aware that this is a reduction in parallel arc protection in the "home run" and considers the trade off in protection, for the sake of making alternative protection devices available in the marketplace acceptable. As with other Code-required products, acceptable alternatives promote competition and new product development.
Public Comment No. 93-NFPA 70-2015 [Section No. 210.12(A)]

(A) Dwelling Units.

All 120-volt, single-phase, 15- and 20-ampere branch circuits supplying outlets or devices installed in dwelling units shall be protected by any of the means described in 210.12(A)(1) through (6):

(1) A listed combination-type arc-fault circuit interrupter, installed to provide protection of the entire branch circuit

(2) A listed branch/feeder-type AFCI installed at the origin of the branch circuit in combination with a listed outlet branch-circuit-type arc-fault circuit interrupter installed at the first outlet box on the branch circuit. The first outlet box in the branch circuit shall be marked to indicate that it is the first outlet of the circuit.

(3) A listed supplemental arc protection circuit breaker installed at the origin of the branch circuit in combination with a listed outlet branch-circuit-type arc-fault circuit interrupter installed at the first outlet box on the branch circuit where all of the following conditions are met:

(4) The branch-circuit wiring shall be continuous from the branch-circuit overcurrent device to the outlet branch-circuit arc-fault circuit interrupter.

(5) The maximum length of the branch-circuit wiring from the branch-circuit overcurrent device to the first outlet shall not exceed 15.2 m (50 ft) for a 14 AWG conductor or 21.3 m (70 ft) for a 12 AWG conductor.

(6) The first outlet box in the branch circuit shall be marked to indicate that it is the first outlet of the circuit.

(7) A listed outlet branch-circuit-type arc-fault circuit interrupter installed at the first outlet on the branch circuit in combination with a listed branch-circuit overcurrent protective device where all of the following conditions are met:

(8) The branch-circuit wiring shall be continuous from the branch-circuit overcurrent device to the outlet branch-circuit arc-fault circuit interrupter.

(9) The maximum length of the branch-circuit wiring from the branch-circuit overcurrent device to the first outlet shall not exceed 15.2 m (50 ft) for a 14 AWG conductor or 21.3 m (70 ft) for a 12 AWG conductor.

(10) The first outlet box in the branch circuit shall be marked to indicate that it is the first outlet of the circuit.

(11) If RMC, IMC, EMT, Type MC, or steel-armored Type AC cables meeting the requirements of 250.118, metal wireways, metal auxiliary gutters, and metal outlet and junction boxes are installed for the portion of the branch circuit between the branch-circuit overcurrent device and the first outlet, it shall be permitted to install a listed outlet branch-circuit-type AFCI at the first outlet to provide protection for the remaining portion of the branch circuit.

(12) Where a listed conduit or tubing or Type MC cable is encased in not less than 50 mm (2 in.) of concrete for the portion of the branch circuit between the branch-circuit overcurrent device and the first outlet, it shall be permitted to install a listed outlet branch-circuit-type AFCI at the first outlet to provide protection for the remaining portion of the branch circuit.

Exception: Where an individual branch circuit to a fire alarm system installed in accordance with 760.41(B) or 760.121(B) is installed in RMC, IMC, EMT, or metal wireways or auxiliary gutters or steel-sheathed cable, Type AC or Type MC, meeting the requirements of 250.118, with metal outlet and junction boxes, AFCI protection shall be permitted to be omitted.

Informational Note No. 1: For information on combination-type and branch/feeder-type arc-fault circuit interrupters, see UL 1699-2011, Standard for Arc-Fault Circuit Interrupters. For information on outlet branch-circuit type arc-fault circuit interrupters, see UL Subject 1699A Outline, Outline of Investigation for Outlet Branch Circuit Arc-Fault Circuit-Interrupters. For information on system combination AFCIs, see UL Subject 1699C, Outline of Investigation for System Combination Arc-Fault Circuit Interrupters.

Informational Note No. 2: See 29.6.3(S) of NFPA 72-2013, National Fire Alarm and Signaling Code, for information related to secondary power-supply requirements for smoke alarms installed in dwelling units.

Informational Note No. 3: See 760.41(B) and 760.121(B) for power-supply requirements for fire alarm systems.

Statement of Problem and Substantiation for Public Comment

In informational note 1 corrected reference to UL 1699A Outline, removed reference to UL Subject 1699C which is now part of UL 1699A Outline.

In informational note 2 updated reference to NFPA 72 to 2016.

Public Comment No. 36-NFPA 70-2015 [Section No. 210.12(B)]

(B) Dormitory Units.

All 120-volt, single-phase, 15- and 20-ampere branch circuits supplying outlets and devices installed in dormitory units, bedrooms, living rooms, hallways, closets, bathrooms and similar rooms, shall be protected by a listed arc-fault circuit interrupter meeting the requirements of 210.12(A)(1) through (6) as appropriate.

Statement of Problem and Substantiation for Public Comment

Whereas the need for AFCI protection has been satisfactorily demonstrated, expanding its application throughout the dormitory unit is consistent with the companion change proposed in 210.12(A).

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-320-NFPA 70-2015
Statement: "As appropriate" is a vague and unenforceable term. It has been deleted in accordance with NEC Style Manual Section 3.2.1. As previously worded, the arc-fault circuit-interrupter could be required to meet all of the requirements of 210.12(A)(1) through 210.12(A)(6). Revised wording matches how 210.12(A) expresses the same.
Public Comment No. 676-NFPA 70-2015 [Section No. 210.12(B)]

(B) Dormitory Units.
All 120-volt, single-phase, 15- and 20-ampere branch circuits supplying outlets and devices installed in dormitory unit bedrooms, living rooms, hallways, closets, bathrooms, kitchens, and similar rooms shall be protected by a listed arc-fault circuit interrupter meeting the requirements of 210.12(A)(1) through (6) as appropriate.

Statement of Problem and Substantiation for Public Comment
We recently experienced a costly fire event in a college dormitory kitchen walk-in refrigerator. A section of heat tracing cable starting arcing but did not trip the circuit breaker. The fault escalated into sparks and fire igniting stored items. A dry sprinkler fused and discharged inside the walk-in refrigerator. The incident caused a significant damage to a central college dormitory, closing the facility.
I believe an AFCI may have prevented the incident. Code section 210.12 (A) Dwelling Units includes kitchen circuits. Code section 210.12 (C) should include kitchens as well.

Committee Statement
Committee Action: Rejected
Resolution: A dormitory unit with a kitchen in the dormitory is a dwelling unit, and AFCI protection is already addressed in 210.12 (A). The location selected for this language in dormitory units would not address the situation which the submitter highlighted. Section 210.12(B) is not the appropriate location for this language (the addition of kitchens) to address the concerns of the submitter.
Public Comment No. 815-NFPA 70-2015 [ Section No. 210.12(B) ]

(B) Dormitory Units.

All 120-volt, single-phase, 15- and 20-ampere branch circuits supplying outlets and devices installed in dormitory unit bedrooms, living rooms, hallways, closets, bathrooms, and similar rooms shall be protected by a listed arc-fault circuit interrupter meeting the requirements of any of the means described in 210.12(A)(1) through (6), as appropriate.

Statement of Problem and Substantiation for Public Comment

“As appropriate” is a vague and unenforceable term. Delete in accordance with NEC® Style Manual 3.2.1. As worded, the arc-fault circuit-interrupter could be required to meet ALL of the requirements of 210.12(A)(1) through 210.12(A)(6). Revise wording to match how 210.12(A) expresses the same. All means in 210.12(A)(1) through 210.12(A)(6) are already specified as being listed; redundant to repeat here.

Resolution: SR-320-NFPA 70-2015
Statement: “As appropriate” is a vague and unenforceable term. It has been deleted in accordance with NEC Style Manual Section 3.2.1. As previously worded, the arc-fault circuit-interrupter could be required to meet all of the requirements of 210.12(A)(1) through 210.12(A)(6). Revised wording matches how 210.12(A) expresses the same.
(C) Branch Circuit Extensions or Modifications — Dwelling Units and Dormitory Units.

In any of the areas specified in 210.12(A) or 210.12(C), where branch-circuit wiring is modified, replaced, or extended, the branch circuit shall be protected by one of the following:

1. A listed combination-type AFCI located at the origin of the branch circuit
2. A listed outlet branch-circuit type-AFCI located at the first receptacle outlet of the existing branch circuit

Exception: AFCI protection shall not be required where the extension of the existing conductors is not more than 1.8 m (6 ft) and does not include any additional outlets or devices.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs that section 210.12(D) be rewritten with respect to "as appropriate" to comply with the NEC Style Manual.

Committee Statement

Committee Action: Rejected
Resolution: This is not already covered in 210.60. Section 210.17 is in Part I of Article 210 which pertains to general provisions. Section 210.60 is in Part III which pertains to required outlets.
210.19 Conductor — Minimum Ampacity and Size.

(A) Branch Circuits Not More Than 600 Volts.

Informational Note No. 1: See 310.15 for ampacity ratings of conductors.

Informational Note No. 2: See Part II of Article 430 for minimum rating of motor branch-circuit conductors.

Informational Note No. 3: See 310.15(A)(3) for temperature limitation of conductors.

Informational Note No. 4: Conductors for branch circuits as defined in Article 100, sized to prevent a voltage drop exceeding 3 percent at the farthest outlet of power, heating, and lighting loads, or combinations of such loads, and where the maximum total voltage drop on both feeders and branch circuits to the farthest outlet does not exceed 5 percent, provide reasonable efficiency of operation. See Informational Note No. 2 of 215.2(A)(1) for voltage drop on feeder conductors.

(1) General.

Branch-circuit conductors shall have an ampacity not less than the maximum load to be served. Conductors shall be sized to carry not less than the larger of 210.19(A)(1)(a) or (b).

(a) Where a branch circuit supplies continuous loads or any combination of continuous and noncontinuous loads, the minimum branch-circuit conductor size shall have an allowable ampacity not less than the noncontinuous load plus 125 percent of the continuous load.

(b) The minimum branch-circuit conductor size shall have an allowable ampacity not less than the maximum load to be served after the application of any adjustment or correction factors.

Exception: If the assembly, including the overcurrent devices protecting the branch circuit(s), is listed for operation at 100 percent of its rating, the allowable ampacity of the branch-circuit conductors shall be permitted to be not less than the sum of the continuous load plus the noncontinuous load.

(2) Branch Circuits with More Than One Receptacle.

Conductors of branch circuits supplying more than one receptacle for cord-and-plug-connected portable loads shall have an ampacity of not less than the rating of the branch circuit.

(3) Household Ranges and Cooking Appliances.

Branch-circuit conductors supplying household ranges, wall-mounted ovens, counter-mounted cooking units, and other household cooking appliances shall have an ampacity not less than the rating of the branch circuit and not less than the maximum load to be served. For ranges of 8 3/4 kW or more rating, the minimum branch-circuit rating shall be 40 amperes.

Exception No. 1: Conductors tapped from a 50-ampere branch circuit supplying electric ranges, wall-mounted electric ovens, and counter-mounted electric cooking units shall have an ampacity of not less than 20 amperes and shall be sufficient for the load to be served. These tap conductors include any conductors that are a part of the leads supplied with the appliance that are smaller than the branch-circuit conductors. The taps shall not be longer than necessary for servicing the appliance.

Exception No. 2: The neutral conductor of a 3-wire branch circuit supplying a household electric range, a wall-mounted oven, or a counter-mounted cooking unit shall be permitted to be smaller than the ungrounded conductors where the maximum demand of a range of 8 3/4-kW or more rating has been calculated according to Column C of Table 220.55, but such conductor shall have an ampacity of not less than 70 percent of the branch-circuit rating and shall not be smaller than 10 AWG.

(4) Other Loads.

Branch-circuit conductors that supply loads other than those specified in 210.3 and other than cooking appliances as covered in 210.19(A)(3) shall have an ampacity sufficient for the loads served and shall not be smaller than 14 AWG.

Exception No. 1: Tap conductors shall have an ampacity sufficient for the load served. In addition, they shall have an ampacity of not less than 15 for circuits rated less than 40 amperes and not less than 20 for circuits rated at 40 or 50 amperes and only where these tap conductors supply any of the following loads:

(a) Individual lampholders or luminaires with taps extending not longer than 450 mm (18 in.) beyond any portion of the lampholder or luminaire

(b) A luminaire having tap conductors as provided in 410.117

(c) Individual outlets, other than receptacle outlets, with taps not over 450 mm (18 in.) long

(d) Infrared lamp industrial heating appliances

(e) Nonheating leads of deicing and snow-melting cables and mats

Exception No. 2: Fixture wires and flexible cords shall be permitted to be smaller than 14 AWG as permitted by 240.5.

(B) Branch Circuits Over 600 Volts.
The ampacity of conductors shall be in accordance with 310.15 and 310.60, as applicable. Branch-circuit conductors over 600 volts shall be sized in accordance with 210.19(B)(1) or (B)(2).

(1) General.

The ampacity of branch-circuit conductors shall not be less than 125 percent of the designed potential load of utilization equipment that will be operated simultaneously.

(2) Supervised Installations.

For supervised installations, branch-circuit conductor sizing shall be permitted to be determined by qualified persons under engineering supervision. Supervised installations are defined as those portions of a facility where both of the following conditions are met:

(1) Conditions of design and installation are provided under engineering supervision.

(2) Qualified persons with documented training and experience in over 600-volt systems provide maintenance, monitoring, and servicing of the system.

Statement of Problem and Substantiation for Public Comment

I agree with the Panel's statement for PI 1268, that two separate comparisons are required to size the conductor properly. I still maintain that the current text is confusing. I would first ask the Panel if there is a difference between ampacity, which is defined in Article 100, and allowable ampacity which is not. I have asked numerous users of the Code to read the current text of 210.19(A) and describe the difference between allowable ampacity and ampacity. The majority respond that an ampacity is read from a table in 310.15 such as Table 310.15(B)(16), and an allowable ampacity results from considering conditions of use and applying adjustment and correction factors. Although this is incorrect and actually backwards, the language in the text of 210.19(A)(1)(b) of "an allowable ampacity not less than the maximum load to be served after the application of any adjustment or correction factors." leads users of the Code to believe an allowable ampacity results from considering conditions of use. Again, this is incorrect. If ampacity is defined in Article 100 as considering the conditions of use, and an allowable ampacity is from an allowable ampacity table in 310.15 such as Table 310.15(B)(16), how can there be an allowable ampacity after conditions of use? After conditions of use and adjustment and correction factors have been applied, is not the result an ampacity, not an allowable ampacity? The current charging text of 210.19(A)(1) requires the conductor to have an ampacity not less than the maximum load to be served. How is the intent of that statement any different than the intent of 210.19(A)(1)(b)? I have proposed removing text in the charging language of 210.19(A)(1), only as it seems to be redundant with 210.19(A)(1)(b), it would be fine if it remained. In 210.19(A)(1)(b), I have removed the word allowable as the current text is technically incorrect and inconsistent with the definition of ampacity and allowable ampacity tables of 310.15 and it is causing confusion. If the panel disagrees, then I ask for the Panel to clarify the two separate comparisons by defining the difference between ampacity and allowable ampacity as used in this section since both terms are used.

Committee Statement

Committee Action: Rejected
Resolution: The charging sentence establishes the fundamental requirement for sizing a conductor to serve the load and needs to remain. Removing the word "allowable" will create further confusion and inconsistency. The ampacity must be calculated in accordance with 310.15. Also see Informational Note in 310.15(B) for an explanation of allowable ampacity.
Public Comment No. 54-NFPA 70-2015 [Section No. 210.52(A)(2)]

(2) Wall Space.

As used in this section, a wall space shall include the following:

1. Any space 600 mm (2 ft) or more in width (including space measured around corners) and unbroken along the floor line by doorways and similar openings, fireplaces, and fixed cabinets that do not have countertops or work surfaces.
2. The space occupied by fixed panels in walls, excluding sliding panels.
3. The space afforded by fixed room dividers, such as freestanding bar-type counters or railings.

Statement of Problem and Substantiation for Public Comment

To correlate with 210.52(C)(5). First Revision FR 308 to 210.52(C)(5) raised the issue of installation of receptacles in work surfaces by revising the Information Note to additionally include work surfaces. The Committee Statement for First Revision FR324 nonetheless makes it clear that the intent is not to address kitchen countertops alone.

Consequently, 210.52(C)(5), 210.52(A)(2), 210.52(A)(4), and 210.52(C) need to include requirements for receptacles outlets in work surfaces.

Committee Statement

Committee Action: Rejected but see related SR
Statement: The addition of "similar work surfaces" was made to provide clarity and inclusion of these types of surfaces that may also be found in the areas identified in 210.52(A) in addition to countertops, as being counted as wall space.
(2) Wall Space.

As used in this section, a wall space shall include the following:

1. Any space 600 mm (2 ft) or more in width (including space measured around corners) and unbroken along the floor line by doorways and similar openings, fireplaces, and fixed cabinets that do not have countertops and fireplaces.

2. The space occupied by fixed panels in walls, excluding sliding panels.

3. The space afforded by fixed room dividers, such as freestanding bar-type counters or railings.

Statement of Problem and Substantiation for Public Comment

All the CMP 2 discussion that resulted in the term "fixed cabinets" being added in 2011 was directly related to the receptacle outlets provided for the wall spaces above the countertops in kitchens, pantries, breakfast rooms and dining rooms. This was not to say the receptacle outlet could not be used for an appliance that was not located on the countertop, say a vacuum cleaner, but that the receptacle outlet would not qualify as the required receptacle outlet for an adjacent wall space. There is no doubt the 2011 action created the unintended consequence of eliminating the requirement for a receptacle outlet in rooms such as libraries which had fixed cabinets around the entire floor line of the room.

CMP 2 attempted to address the situation in the First Draft by adding the words "without countertops" to 210.52(A)(2)(1) which does not correct the unintended consequences of 2011 and will add additional confusion. What qualifies as a "countertop" in a library or a den?

Section 210.52(A)(4) already restricts receptacle outlets above countertops in kitchens, pantries, breakfast rooms and dining rooms from qualifying for adjacent wall spaces so the 2011 action was unnecessary. Removing "and fixed cabinets without countertops" from 210.52(A)(2)(1) will address the unintended consequences of the 2011 action without compromising the intent of the First Draft revision.

Committee Statement

Committee Action: Rejected

Resolution: The proposed change would return the language of 210.52(A)(2) to its original language of NEC 2011 as this would create the same problem was addressed when 210.52(A)(4) was added in that same cycle. The addition of 210.52(A)(4) was substantiated as follows: "Required countertop receptacles cannot be used to comply with wall space requirements, an example is a 3 ft wall space between the end of a counter and a door, that wall space needs a receptacle and cannot use a countertop receptacle to comply." The changes in 210.52(A)(2) were to address that with the addition of 210.52(A)(4) a change would be required to 210.52(A)(2) which identifies wall space as any space that meets a dimension and is unbroken along the floor line by doors and similar openings. The submitted noted that “... without this added text the “unbroken floor line” would include the floor line in front of the kitchen cabinets.” Additional outlet receptacles are not required in front of kitchen cabinets or other similar work surfaces that already have requirements as per other areas of the NEC. Hence the change was made in 210.52(A)(2) to include countertops.
Public Comment No. 55-NFPA 70-2015 [Section No. 210.52(A)(4)]

(4) Countertop Receptacles and Work Surface Receptacle Outlets.

Receptacles installed for countertop countertops and work surfaces as specified in 210.52(C) shall not be considered as the receptacles, receptacle outlets, required by 210.52(A).

Statement of Problem and Substantiation for Public Comment

To avoid confusion and misinterpretations, and improve readability of the Code.

First Revision FR 308 to 210.52(C)(5) raised the issue of installation of receptacles in work surfaces by revising the Information Note to additionally include work surfaces. The Committee Statement for First Revision FR324 nonetheless makes it clear that the intent is not to address kitchen countertops alone.

Consequently, 210.52(C)(5), 210.52(A)(2), 210.52(A)(4), and 210.52(C) need to include requirements for receptacles outlets in work surfaces.

Committee Statement
Committee Action: Rejected but see related SR
Statement: The addition of "similar work surfaces" was made to provide clarity and inclusion of these types of surfaces that may also be found in the areas identified in 210.52(A) in addition to countertops, as being counted as wall space.
Receptacle Outlets Served.

In the kitchen, pantry, breakfast room, dining room, or similar area of a dwelling unit, the two or more 20-ampere small-appliance branch circuits required by 210.11(C)(1) shall serve all wall and floor receptacle outlets covered by 210.52(A), all countertop outlets covered by 210.52(C), and receptacle outlets for refrigeration equipment.

Exception No. 1: In addition to the required receptacles specified by 210.52, switched receptacles supplied from a general-purpose branch circuit as defined in 210.70(A)(1), Exception No. 1, shall be permitted.

Exception No. 2: The receptacle outlet for refrigeration equipment shall be permitted to be supplied from an individual branch circuit rated 15 amperes or greater.

Exception No. 3: A single receptacle dedicated to a specific appliance supplied by an individual branch circuit.

Statement of Problem and Substantiation for Public Comment

Apparently the Panel failed in the substantiation to notice their response was contradicted by Exception No. 3 in this same Section. The Exception for refrigerators was added to allow the 15-ampere outlet and not to be bound by the small appliance circuit receptacle rule. Certain appliances are installed on dedicated circuits by cord and plug connections in the kitchen area regularly. The refrigerator Exception is the only permitted non-small appliance circuit supplied now for other appliances. There is no link stating that the individual branch circuit may be permitted as an Exception, as they have indicated.

Submittal Date: Wed Sep 23 10:01:19 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-308-NFPA 70-2015
Statement: This change made to Exception No. 2 recognizes that an individual branch circuit supplied specifically for any single appliance is allowed to be a 15-ampere receptacle outlet.
(C) Countertops and Work Surfaces.

In kitchens, pantries, breakfast rooms, dining rooms, and similar areas of dwelling units, receptacle outlets for countertop and work surface spaces shall be installed in accordance with 210.52(C)(1) through (C)(5).

(1) Wall Countertop and Work Surface Spaces.

A receptacle outlet shall be installed at each wall countertop and work surface space that is 300 mm (12 in.) or wider. Receptacle outlets shall be installed so that no point along the wall line is more than 600 mm (24 in.) measured horizontally from a receptacle outlet in that space.

Exception: Receptacle outlets shall not be required on a wall directly behind a range, counter-mounted cooking unit, or sink in the installation described in Figure 210.52(C)(1).

Figure 210.52(C)(1) Determination of Area Behind a Range, or Counter-Mounted Cooking Unit or Sink.

(2) Island Countertop Spaces.

At least one receptacle shall be installed at each island countertop space with a long dimension of 600 mm (24 in.) or greater and a short dimension of 300 mm (12 in.) or greater.

(3) Peninsular Countertop Spaces.

At least one receptacle outlet shall be installed at each peninsular countertop long dimension space with a long dimension of 600 mm (24 in.) or greater and a short dimension of 300 mm (12 in.) or greater. A peninsular countertop is measured from the connected perpendicular wall.

A receptacle in a wall countertop space shall be permitted to serve as the receptacle for a peninsular countertop space where the spaces are contiguous and the receptacle is located within 1.8 m (6 ft) of the outside edge of the peninsular countertop.
(4) Separate Spaces.
Countertop spaces separated by rangetops, refrigerators, or sinks shall be considered as separate countertop spaces in applying the requirements of 210.52(C)(1). If a range, counter-mounted cooking unit, or sink is installed in an island or peninsular countertop and the depth of the countertop behind the range, counter-mounted cooking unit, or sink is less than 300 mm (12 in.), the range, counter-mounted cooking unit, or sink shall be considered to divide the countertop space into two separate countertop spaces. Each separate countertop space shall comply with the applicable requirements in 210.52(C).

(5) Receptacle Outlet Location.
Receptacle outlets shall be located on or above, but not more than 500 mm (20 in.) above, the countertop. Receptacle outlet assemblies listed for use in countertops shall be permitted to be installed in countertops. Receptacle outlets rendered not readily accessible by appliances fastened in place, appliance garages, sinks, or rangetops as covered in 210.52(C)(1), Exception, or appliances occupying dedicated space shall not be considered as these required outlets.

Informational Note: See 406.5(E) for requirements for installation of receptacles in countertops and 406.5(F) for requirements for installation in work surfaces.

Exception to (5): To comply with the conditions specified in (1) or (2), receptacle outlets shall be permitted to be mounted not more than 300 mm (12 in.) below the countertop. Receptacles mounted below a countertop in accordance with this exception shall not be located where the countertop extends more than 150 mm (6 in.) beyond its support base.

(1) Construction for the physically impaired
(2) On island and peninsular countertops where the countertop is flat across its entire surface (no backsplashes, dividers, etc.) and there are no means to mount a receptacle within 500 mm (20 in.) above the countertop, such as an overhead cabinet

Statement of Problem and Substantiation for Public Comment
To avoid confusion and misinterpretations, and improve readability of the Code.

First Revision FR 308 to 210.52(C)(5) raised the issue of installation of receptacles in work surfaces by revising the Information Note to additionally include work surfaces. The Committee Statement for First Revision FR324 nonetheless makes it clear that the intent is not to address kitchen countertops alone.

Consequently, 210.52(C)(5), 210.52(A)(2), 210.52(A)(4), and 210.52(C) need to include requirements for receptacles outlets in work surfaces.

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-309-NFPA 70-2015 Additional TC Statement for PC#58: The removal of language as part of 210.52(C)(5) requiring listed solutions for countertop or work surface applications was not accepted as sufficient substantiation was not provided that would support this action. Additional TC Statement for PC#56: The removal of language as part of 210.52(C) for the locations kitchens, pantries, breakfast rooms, dining rooms, and similar areas was not accepted as sufficient substantiation was not provided that would support this action.
Statement: The addition of “work surfaces” was made to align with changes in 210.52(A) and to add clarity.

The language in 210.52(C)(3) was modified to not create language that reduces the coverage of receptacles but rather to better define how a peninsular countertop is measured for clarity or when additional receptacles to serve the peninsular countertop space should be provided.
(3) Peninsular Countertop Spaces.

At least one receptacle outlet shall be installed at each peninsular countertop long dimension space with a long dimension of 600 mm (24 in.) or greater and a short dimension of 300 mm (12 in.) or greater. A peninsular countertop is measured from the connected perpendicular wall, outer end to the connection to the perpendicular countertop surface.

A receptacle in a wall countertop space shall be permitted to serve as the receptacle for a peninsular countertop space where the spaces are contiguous and the receptacle is located within 1.8 m (6 ft) of the outside edge, end, of the peninsular countertop.

Statement of Problem and Substantiation for Public Comment

The original wording was unclear. A peninsular counter does not always connect to a wall but sometimes connects to another counter. The comment hopefully suggests clearer wording.

Statement of Problem and Substantiation for Public Comment

I urge CMP-2 to accept this Public Comment and return this Code language to its previous text in the 2014 NEC. By accepting the Public Input and First Revision at 210.52(C)(3), safety for the user (typically the homeowner) is lessened from the previous requirements for a receptacle at a peninsular countertop. The language accepted at the First Draft stage would allow a receptacle outlet at the connecting wall (which serves the base countertop) to also serve the peninsular countertop. The end of the peninsular countertop could be as far away from the wall receptacle as 1.8 m (6 ft). Under the 2014 NEC, a peninsular countertop that measures 600 mm (24 in.) by 900 mm (36 in.) (measured from the connecting edge) would require at least one receptacle outlet (located at the peninsular countertop) to serve that peninsular countertop. Under the proposed text of the 2017 NEC, this same peninsular countertop would require ZERO receptacles at the peninsular countertop as the countertop could be served by the wall receptacle [that could be up to 1.8 m (6 ft) away from the end of said countertop].

The language in 210.52(C)(3) was modified to not create language that reduces the coverage of receptacles but rather to better define how a peninsular countertop is measured for clarity or when additional receptacles to serve the peninsular countertop space should be provided.
Public Comment No. 58-NFPA 70-2015 [Section No. 210.52(C)(5)]

(5) Countertop and Work Surface Receptacle Outlet Location.

Receptacle outlets shall be located on or above, but not more than 500 mm (20 in.) above, the countertop or work surface. Receptacle outlet assemblies listed for use in countertops shall be permitted to be installed in countertops. Receptacle outlets rendered not readily accessible by appliances fastened in place, appliance garages, sinks, or rangetops as covered in 210.52(C)(1). Exception, or appliances occupying dedicated space shall not be considered as these required outlets.

Informational Note: See 406.5(E) and 406.5(G) for requirements for installation of receptacles in countertops and 406.5(F) and 406.5(G) for requirements for installation of receptacles in work surfaces.

Exception to (5): To comply with the conditions specified in (1) or (2), receptacle outlets shall be permitted to be mounted not more than 300 mm (12 in.) below the countertop or work surface. Receptacles mounted below a countertop or work surface in accordance with this exception shall not be located where the countertop or work surface extends more than 150 mm (6 in.) beyond its support base.

(1) Construction for the physically impaired
(2) On island and peninsular countertops where the countertop is flat across its entire surface (no backsplashes, dividers, etc.) and there are no means to mount a receptacle within 500 mm (20 in.) above the countertop, such as an overhead cabinet

Statement of Problem and Substantiation for Public Comment

First Revision FR 308 to 210.52(C)(5) as written will add confusion, and reduce readability of the Code, and result in misinterpretations.

210.52(C)(5) by its title is intended to specify the LOCATION of REQUIRED countertop receptacle outlets, not the TYPE of eligible receptacles or receptacle assemblies already covered in 406.5(E) in 2014 NEC® [First Revision FR5108 divides that 406.5(E) into 406.5(E), (F) and (G) and renumbers the remainder for the 2017 NEC®]. The Informational Note already directs the reader to 406.5(E); that Information Note, however, DOES need to be correlated with FR 5108 for the requirements now separated off into NEW 406.5(G). The second sentence of the mandatory requirement is nonetheless redundant to the mandatory requirement of referenced 406.5(E) and should therefore be deleted.

First Revision FR 308 to 210.52(C)(5) raised the issue of installation of receptacles in work surfaces by revising the Information Note to additionally include work surfaces. Nothing in the MANDATORY requirements of 210.52(C)(5) however addresses WORK SURFACE receptacle outlets as being REQUIRED outlets or imposes any location requirements upon WORK SURFACE receptacle outlets. The Committee Statement for First Revision FR324 nonetheless makes it clear that the intent is not to address kitchen countertops alone.

Consequently, 210.52(C)(5), 210.52(A)(2), 210.52(A)(4), and 210.52(C) need to include requirements for receptacles outlets in work surfaces.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-309-NFPA 70-2015 Additional TC Statement for PC#58: The removal of language as part of 210.52(C)(5) requiring listed solutions for countertop or work surface applications was not accepted as sufficient substantiation was not provided that would support this action. Additional TC Statement for PC#56: The removal of language as part of 210.52(C) for the locations kitchens, pantries, breakfast rooms, dining rooms, and similar areas was not accepted as sufficient.
substantiation was not provided that would support this action.

**Statement:** The addition of "work surfaces" was made to align with changes in 210.52(A) and to add clarity.

The language in 210.52(C)(3) was modified to not create language that reduces the coverage of receptacles but rather to better define how a peninsular countertop is measured for clarity or when additional receptacles to serve the peninsular countertop space should be provided.
(5) Receptacle Outlet Location.

Receptacle outlets shall be located on or above, but not more than 500 mm (20 in.) above, the countertop. Receptacle outlet assemblies listed for use in countertops shall be permitted to be installed in countertops. Receptacle outlet assemblies listed for use in countertops or work surfaces shall be permitted to be installed in work surfaces. Receptacle outlets rendered not readily accessible by appliances fastened in place, appliance garages, sinks, or rangetops as covered in 210.52(C)(1), Exception, or appliances occupying dedicated space shall not be considered as these required outlets.

Informational Note: See 406.5(E) and 406.5(G) for requirements for installation of receptacles in countertops and 406.5(F) and 406.5(G) for requirements for installation of receptacles in work surfaces.

Exception to (5): To comply with the conditions specified in (1) or (2), receptacle outlets shall be permitted to be mounted not more than 300 mm (12 in.) below the countertop. Receptacles mounted below a countertop in accordance with this exception shall not be located where the countertop extends more than 150 mm (6 in.) beyond its support base.

(1) Construction for the physically impaired

(2) On island and peninsular countertops where the countertop is flat across its entire surface (no backsplashes, dividers, etc.) and there are no means to mount a receptacle within 500 mm (20 in.) above the countertop, such as an overhead cabinet

Statement of Problem and Substantiation for Public Comment

The First Revision FR 308 to 210.52(C)(5) raised the issue of installation of receptacles in work surfaces by revising the Information Note to additionally include work surfaces. Consequently, 210.52(C)(5) need to correlate to First Revision FR5108 that divides 406.5(E) into 406.5(E), (F) and (G) and renumbers the remainder for the 2017 NEC®, to include requirements for receptacles in work surfaces.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-309-NFPA 70-2015 Additional TC Statement for PC#58: The removal of language as part of 210.52(C)(5) requiring listed solutions for countertop or work surface applications was not accepted as sufficient substantiation was not provided that would support this action. Additional TC Statement for PC#56: The removal of language as part of 210.52(C) for the locations kitchens, pantries, breakfast rooms, dining rooms, and similar areas was not accepted as sufficient substantiation was not provided that would support this action.

Statement: The addition of “work surfaces” was made to align with changes in 210.52(A) and to add clarity.

The language in 210.52(C)(3) was modified to not create language that reduces the coverage of receptacles but rather to better define how a peninsular countertop is measured for clarity or when additional receptacles to serve the peninsular countertop space should be provided.
(D) Bathrooms.

At least one receptacle outlet shall be installed in bathrooms within 900 mm (3 ft) of the outside edge of each basin. The receptacle outlet shall be located on a wall or partition that is adjacent to the basin or basin countertop, located on the countertop, or installed on the side or face of the basin cabinet. In no case shall the receptacle be located more than 300 mm (12 in.) below the top of the basin or basin countertop. Receptacle outlet assemblies listed for the application shall be permitted to be installed in the countertop.

Informational Note: See 406.5(E) and 406.5(G) for requirements for installation of receptacles in countertops.

Statement of Problem and Substantiation for Public Comment

“Listed for the application” is considered to be a vague and unenforceable term per the NEC® Style Manual Clause 3.2.1. The First Revision FR 308 to 210.52(C)(5) revised “Receptacle outlet assemblies listed for the application …” to “Receptacle outlet assemblies listed for use in countertops …”. FR 309 should similarly revise 210.52(D), for consistency. BUT …

210.52(D) is intended to specify the LOCATION of REQUIRED countertop receptacle outlets, not the TYPE of eligible receptacles or receptacle assemblies ALREADY covered in 406.5(E) in 2014 NEC® [First Revision FR5108 divides that 406.5(E) into 406.5(E), (F) and (G) and renumbers the remainder for the 2017 NEC®]. The Informational Note already directs the reader to 406.5(E); that Informational Note, however, DOES need to be correlated with FR 5108 for the requirements now separated off into NEW 406.5(G). The third sentence of the mandatory requirement is nonetheless redundant to the mandatory requirement of referenced 406.5(E) and should therefore be deleted.

Additionally, FR 309 shows a sentence-case “At” being added to the start of this requirement but did not delete the lowercase “at”, resulting in “At at …”.

Resolution: SR-310-NFPA 70-2015 Additional TC statement for PC#59: The removal of language as part of 210.52(D) requiring listed solutions for countertops was not accepted as sufficient substantiation was not provided that supports this action.
Statement: For clarity, “listed for the application” was replaced with “listed for use in countertops”.

The addition of 406.5(G) in the informational note correlates with changes made in the First Revision for requirements that were separated into a new 406.5(G)
Outdoor receptacle outlets shall be installed in accordance with 210.52(E)(1) through (E)(3). When an addition is made to an existing dwelling which includes the addition of receptacle outlets required in accordance with 210.52(A), at least one exterior GFCI receptacle outlet shall be provided.

Informational Note: See 210.8(A)(3).

Statement of Problem and Substantiation for Public Comment

The intent is to require that when an addition is being made including electrical work for the addition, the finished building shall be provided with an exterior protected (GFCI) outlet. This could be an existing exterior receptacle outlet that is changed to include GFCI, or it could be a whole new exterior receptacle outlet with GFCI.

Committee Statement

Committee Action: Rejected
Resolution: Substantiation was not provided that warrant the addition of an exterior GFCI receptacle outlet any time a change is made anywhere in the structure that adds a receptacle outlet in accordance with 210.52(A).
Exception.
A receptacle outlet shall not be required if no walking surface is available and the receptacle outlet cannot be installed accessible from the opening leading to the balcony, deck or porch.

Statement of Problem and Substantiation for Public Comment
the receptacle cannot be reached in this type of installation Please see photo attached, an exception should be provide for this situation.

Related Item
Public Input No. 4235-NFPA 70-2014 [Section No. 210.52(3)]

Committee Statement
Committee Action: Rejected
Resolution: The proposed exception could promote the use of extension cords through doors and windows.
(1) Garages.
In each attached garage and in each detached garage with electric power, the branch circuit supplying this receptacle(s) shall not supply outlets outside of the garage. At least one receptacle outlet shall be installed in each vehicle bay and not more than 1.7 m (5 1/2 ft) above the floor.

Exception: Recepticals required by 210.52 (E) shall be permitted to be supplied by this branch circuit.

Statement of Problem and Substantiation for Public Comment

There is no adequate substantiation to support that other receptacles should not be allowed on this circuit. Article 210.11(C)(3) will now require this circuit to be a 20 amp circuit. A power tool that draws 16 amps was used as substantiation in the FR. Power tools are seldom used in the average homeowner’s garage. Hair dryers that draw 16 amps are more likely to be used in bathrooms and at times more than one at the same because of multiple bathrooms. The NEC does not require individual branch circuits to bathrooms.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-326-NFPA 70-2015
Statement: The language related to outlets outside of the garage has been deleted from this section to correlate with changes made to 210.11(C)(4).
Garages.

In each attached garage and in each detached garage with electric power, the branch circuit supplying this receptacle(s) shall not supply outlets outside of the garage. At least one receptacle outlet shall be installed in each vehicle bay and not more than 1.7 m (5 1/2 ft) above the floor.

### Statement of Problem and Substantiation for Public Comment

This is a design issue and not an electrical safety issue and does not belong in the cord. Also it is an attempt to provide power for electrical vehicle charging, but many such charging systems will require more power than required by the rule. Also vehicle bay is an undefined term. It is often considered the area where a vehicle would be parked and/or stored, but may not be defined by a wall where a receptacle could be installed.

- **Submittal Date:** Fri Jul 31 16:53:55 EDT 2015

### Committee Statement

- **Committee Action:** Rejected
- **Resolution:** The existing language in 210.52(G) is not an attempt to provide power for electric vehicle charging but rather for loads typically seen in a garage.
Garages.

In each attached garage and in each detached garage with electric power, the branch circuit supplying this receptacle(s) shall not supply outlets outside of the garage. At least one receptacle outlet shall be installed in each vehicle bay and not more than 1.7 m (5 1/2 ft) above the floor.

Exception: The branch circuit shall be permitted to supply a receptacle outlet(s) on the outside of the garage.

Statement of Problem and Substantiation for Public Comment

Although the exception will restore the option to supply outdoor receptacle outlets on the garage from the required branch circuit inside the garage, the revised wording will restrict lighting or other receptacle outlets from being supplied. The revised text “shall not supply other outlets” is consistent with other language in 210 restricting the use of branch circuits. Additionally, CMP 2 created a minimum requirement of 20 amperes for the garage branch circuit as a means of recognizing the increased use of the circuit for the First Draft. The requirements for the EV charging circuit are not considered by this section as the last sentence of 210.52(G) specifies the required receptacle(s) is in addition to those installed for specific equipment. The type of circuit required for EV charging will be addressed in 625 and/or the manufactures installation instructions for the equipment.

Public Comment No. 954-NFPA 70-2015 [Section No. 210.52(G)(1)]

(1) Garages.
In each attached garage and in each detached garage with electric power, the branch circuit supplying this receptacle(s) shall not supply outlets outside of the garage. At least one receptacle outlet shall be installed in each vehicle bay and not more than 1.7 m (5 1/2 ft) above the floor.

Statement of Problem and Substantiation for Public Comment

A similar requirement for "no other outlets" is being proposed at 210.11(C)(4). Section 210.52 is requirements for dwelling unit receptacle outlets. A more appropriate location for this text that deals with the branch circuit supplying these receptacle outlets is 210.11(C), which deals with required branch circuits for dwelling units. The proposed deleted text deals with the branch circuit supplying the garage, not the receptacle outlet(s) itself.

</tr>
</thead>
<tbody>
<tr>
<td>210_64.jpg</td>
<td>Oil Well Service</td>
<td></td>
</tr>
</tbody>
</table>

**Statement of Problem and Substantiation for Public Comment**

For the sake of consistency with other NEC references, the voltage threshold should be 150 volts, not 120, as 150 is generally used throughout the NEC to refer to wye-connected systems with a line to neutral voltage greater than 120 volts. See 210.13, 215.10, 225.18, 230.24, 230.95, to name a few of many such references.

As proposed, the exception applies to only two categories of many. Removing the references to specific articles permits the exception to be used in any case where there is no 120 volt, nominal system available. Please see attached photo of a recent oil well service I inspected where the electrical contractor had attempted to comply with 210.64, adding over $700. to the project cost, for a receptacle which might never be used.

**Committee Statement**

Committee Action: Rejected  
Resolution: The receptacle required by this section is needed for services greater than 150 volts. The purpose for this receptacle is for the testing and servicing of electrical equipment in the vicinity of the service.
Public Comment No. 1034-NFPA 70-2015 [ Section No. 210.70(A)(3) ]

(3) Storage or Equipment Spaces.
For attics, underfloor spaces, utility rooms, and basements, at least one lighting outlet containing a switch or controlled by a wall switch shall be installed where these spaces are used for storage or contain equipment requiring servicing. At least one point of control shall be at the usual point of entry to these spaces. The lighting outlet shall be provided at or near the equipment requiring servicing. Lamps installed in lighting outlets in these spaces, such as in lamp sockets, shall be protected from physical damage.

Statement of Problem and Substantiation for Public Comment

The protection warranted to prevent electric shock caused by contact from broken lamps would eliminate needs for other forms of required protections such as GFCI or AFCI to be extended in this area. The referenced 2014 death in North Carolina caused by a worker in a crawl space accidently breaking a lamp bulb exposing the worker to contact with 120 volts could have been prevented by a small device such as those accepted in other areas for the same protection being placed over the lamp or bulb.

Code Making Panel 2 had stated that this protection was not under their purview however in other Code Sections the consideration that Luminaires subject to damage are specifically referenced to require protection from damage. The intent of the Public Input was to assure protection from the broken lamp exposing the energized filament.

Committee Statement

Committee Action: Rejected
Resolution: Attics, underfloor spaces, utility rooms, and basements do not provide the same hazards that are found in crawl spaces which can be constricted.
Public Comment No. 985-NFPA 70-2015 [Section No. 210.70(C)]

(C) All Occupancies.
For attics and underfloor spaces, utility rooms, and basements, at least one lighting outlet containing a switch or controlled by a wall switch shall be installed where these spaces are used for storage or contain equipment requiring servicing. At least one point of control shall be at the usual point of entry to these spaces. The lighting outlet shall be provided at or near the equipment requiring servicing.

A lighting outlet installed in a crawl space shall be protected from physical damage or be provided with GFCI protection.

Statement of Problem and Substantiation for Public Comment

Although this requirement has merit, it is related to the type of lampholder or luminaire and should not be located in 210. It should be located in 410 where protection of lampholders, luminaires and their associated lamps are covered. Further, 210.70 is for required lighting outlets and therefore does address lampholders or luminaires. Other than enclosing the conductors, how do you protect a lighting outlet from physical damage? Additionally, providing GFCI protection for the lighting outlet in instead of guarding the lamp from contact by an individual does not address the true hazards of inadvertently contacting a hot lamp or from broken glass.

Resolution: SR-311-NFPA 70-2015
Statement: Lighting outlets installed in crawl spaces shall be provided with GFCI protection. This requirement has been moved to 210.8. Physical protection does not provide the appropriate shock protection.
210.71 - Meeting Rooms.

(A) - General.

Each meeting room in other than dwelling units shall have nonlocking-type, 125-volt, 15- and 20-ampere receptacles installed in accordance with 210.71(B) through (E). Where a room or space is provided with movable partition(s), the room size shall be determined with the partition in the position that results in the smallest size meeting room.

Informational Note No. 1: For the purposes of this section, meeting rooms are typically designed or intended for the gathering of seated occupants for such purposes as conferences, deliberations, or similar purposes, where portable electronic equipment such as computers, projectors, or similar equipment is likely to be used.

Informational Note No. 2: The types of receptacles covered by this requirement are identified as 5-15 and 5-20 in ANSI/NEMA WD 6-2002, National Electrical Manufacturers Association, Standard for Dimensions of Attachment Plugs and Receptacles.

(B) - Receptacle Outlets in Fixed Walls.

In meeting rooms having a floor area of 70 m$^2$ (760 ft$^2$) or less, receptacle outlets shall be installed in accordance with 210.52(A)(1) through (A)(4). These receptacle outlets shall be in addition to any receptacle outlets that are located within cabinets or cupboards, or located more than 1.7 m (5 4/12 ft) above the floor.

(C) - Floor Receptacle Outlets.

A meeting room that is at least 3.6 m (12 ft) wide and that has a floor area of at least 21 m$^2$ (225 ft$^2$) and not more than 70 m$^2$ (760 ft$^2$) shall have at least one duplex- or quadruplex-type receptacle located in the floor at a distance not less than 1.8 m (6 ft) from any fixed wall.

(D) - Receptacle Outlets at Moveable Room Partitions.

At least one floor receptacle outlet shall be installed for each 3.7 linear m (12 linear ft) or major fraction thereof of movable wall measured horizontally along the floor line. These receptacle outlets shall be located within 450 mm (18 in.) of the partition.

(E) - Receptacle Outlet Placement.

In applying the provisions of this section, the total number of receptacle outlets shall not be less than as determined in (B), (C), and (D). The receptacle outlets required by this section shall be permitted to be located in accordance with municipal, state, federal, or other codes and regulations, or as determined by the designer/building owner.

Informational Note No. 1: See Section 314.27(B) for floor boxes used for receptacles located in the floor.

Informational Note No. 2: See Article 518 for assembly occupancies designed for 100 or more persons.

delete section

Statement of Problem and Substantiation for Public Comment

No data or sufficient substantiation was provided that there have been problems or hazards with insufficient receptacles installed in meeting rooms to warrant adding this section. The committee statement was "the new section addresses the inherent life safety concerns relating to inadequate access to electrical power in meeting rooms" If data or substantiation were to be provided it is likely the same issues would still exist as this section is written.

(B). Receptacle Outlets in Fixed Walls.

In meeting rooms having a floor area of 70 m² (760 ft²) or less, receptacle outlets shall be installed in accordance with 210.52(A) (A)(1) through (A)(4). These receptacle outlets shall be in addition to any receptacle outlets that are located within cabinets or cupboards, or located more than 1.7 m (5 1/2 ft) above the floor.

(C). Floor Receptacle Outlets.

A meeting room that is at least 3.6 m (12 ft) wide and that has a floor area of at least 21 m² (225 ft²) and not more than 70 m² (760 ft²) shall have at least one duplex- or quadruplex-type receptacle located in the floor at a distance not less than 1.8 m (6 ft) from any fixed wall.

(D). Receptacle Outlets at Moveable Room Partitions.

At least one floor receptacle outlet shall be installed for each 3.7 linear m (12 linear ft) or major fraction thereof of movable wall measured horizontally along the floor line. These receptacle outlets shall be located within 450 mm (18 in.) of the partition.

(E). Receptacle Outlet Placement.

In applying the provisions of this section, the total number of receptacle outlets shall not be less than as determined in (B), (C), and (D). The receptacle outlets required by this section shall be permitted to be located in accordance with municipal, state, federal, or other codes and regulations, or as determined by the designer/building owner.

Informational Note No. 1: See Section 314.27(B) for floor boxes used for receptacles located in the floor.

Informational Note No. 2: See Article 518 for assembly occupancies designed for 100 or more persons.

Statement of Problem and Substantiation for Public Comment

This is a design issue and is outside of the purpose of the NEC, as described in 90.1(A). Furthermore, the substantiation provided by the submitter (CMP 2) would never have been adequate from anyone other than CMP2. The requirement for providing technical substantiation is proving to be a requirement for everyone but the panel. How many dead bodies are there? How many fires? What were the results of the cost benefit study that was performed? These are questions that panel two asks others, what are panel two’s answers here?

210.71 - Meeting Rooms.

(A) - General.
Each meeting room in other than dwelling units shall have nonlocking-type, 125-volt, 15- and 20-ampere receptacles installed in accordance with 210.71(B) through (E). Where a room or space is provided with movable partition(s), the room size shall be determined with the partition in the position that results in the smallest size meeting room.

Informational Note No. 1: For the purposes of this section, meeting rooms are typically designed or intended for the gathering of seated occupants for such purposes as conferences, deliberations, or similar purposes, where portable electronic equipment such as computers, projectors, or similar equipment is likely to be used.

Informational Note No. 2: The types of receptacles covered by this requirement are identified as 5-15 and 5-20 in ANSI/NEMA WD 6-2002, National Electrical Manufacturers Association, Standard for Dimensions of Attachment Plugs and Receptacles.

(B) - Receptacle Outlets in Fixed Walls.
In meeting rooms having a floor area of 70 m² (760 ft²) or less, receptacle outlets shall be installed in accordance with 210.52(A) (A)(1) through (A)(4). These receptacle outlets shall be in addition to any receptacle outlets that are located within cabinets or cupboards, or located more than 1.7 m (5 1/2 ft) above the floor.

(C) - Floor Receptacle Outlets.
A meeting room that is at least 3.6 m (12 ft) wide and that has a floor area of at least 21 m² (225 ft²) and not more than 70 m² (760 ft²) shall have at least one duplex- or quadruplex-type receptacle located in the floor at a distance not less than 1.8 m (6 ft) from any fixed wall.

(D) - Receptacle Outlets at Moveable Room Partitions.
At least one floor receptacle outlet shall be installed for each 3.7 linear m (12 linear ft) or major fraction thereof of movable wall measured horizontally along the floor line. These receptacle outlets shall be located within 450 mm (18 in.) of the partition.

(E) - Receptacle Outlet Placement.
In applying the provisions of this section, the total number of receptacle outlets shall not be less than as determined in (B), (C), and (D). The receptacle outlets required by this section shall be permitted to be located in accordance with municipal, state, federal, or other codes and regulations, or as determined by the designer/building owner.

Informational Note No. 1: See Section 314.27(B) for floor boxes used for receptacles located in the floor.

Informational Note No. 2: See Article 518 for assembly occupancies designed for 100 or more persons.

Statement of Problem and Substantiation for Public Comment

Three concerns were raised during the balloting, that BOMA agrees should be revisited by the committee during the second draft meeting. First and foremost is the fact that there was no substantiation or data presented to the committee or to the public to justify this design requirement being incorporated into the National Electrical Code, nor does the proposed language cure the perceived problem on meeting rooms not being provided with properly located receptacles to eliminate the use of extension cords. By design, conference and meeting rooms serve the function of providing work space to conduct business. To assume that a building owner or designer is not going to provide receptacles in these locations is ludicrous, businesses and tenants need electricity to function and power will be provided.

The new code language also does not address the concern about eliminating the reliance on extension cords. Depending on the function of the space and furniture configurations, the receptacles may still be in a location where the use of extension cords will be needed and based on the number of occupants needing power may require additional power strips. In addition, based on the 210.71(E) the designer can take the total number of receptacles required by (B), (C) & (D) and lump them all in one single location and extensions cords will still be used. Along with creating confusion referring the designer to go to the dwelling unit receptacle outlets for meeting room receptacles, the requirements for the installing these receptacles in accordance with 210.52 (A)(1)- (4), was not justified, analyzed or supported by any data to support the need for meeting rooms to follow the same installation requirements for residential dwellings. BOMA encourages the committee to remove this language and continue to allow designers and architects the ability to design these rooms without these arbitrary restraints.

### Public Comment No. 790-NFPA 70-2015 [Section No. 210.71]

#### 210.71 Meeting Rooms

**(A) General.**

Each meeting room in other than dwelling units shall have nonlocking-type, 125-volt, 15- and 20-ampere receptacles installed in accordance with **210.71(B)** through (E). Where a room or space is provided with movable partition(s), the room size shall be determined with the partition in the position that results in the smallest size meeting room.

**Informational Note No. 1:** For the purposes of this section, meeting rooms are typically designed or intended for the gathering of seated occupants for such purposes as conferences, deliberations, or similar purposes, where portable electronic equipment such as computers, projectors, or similar equipment is likely to be used.

**Informational Note No. 2:** The types of receptacles covered by this requirement are identified as 5-15 and 5-20 in ANSI/NEMA WD 6-2002, National Electrical Manufacturers Association, Standard for Dimensions of Attachment Plugs and Receptacles.

**(B) Receptacle Outlets in Fixed Walls.**

In meeting rooms having a floor area of 70 m² (760 ft²) or less, receptacle outlets shall be installed in accordance with **210.52(A)** (A)(1) through (A)(4). These receptacles outlets shall be in addition to any receptacle outlets that are located within cabinets or cupboards, or located more than 1.7 m (5 4/12 ft) above the floor.

**(C) Floor Receptacle Outlets.**

A meeting room that is at least 3.6 m (12 ft) wide and that has a floor area of at least 21 m² (225 ft²) and not more than 70 m² (760 ft²) shall have at least one duplex- or quadruplex-type receptacle located in the floor at a distance not less than 1.8 m (6 ft) from any fixed wall.

**(D) Receptacle Outlets at Moveable Room Partitions.**

At least one floor receptacle outlet shall be installed for each 3.7 linear m (12 linear ft) or major fraction thereof of movable wall measured horizontally along the floor line. These receptacle outlets shall be located within 450 mm (18 in.) of the partition.

**(E) Receptacle Outlet Placement.**

In applying the provisions of this section, the total number of receptacle outlets shall not be less than as determined in (B), (C), and (D). The receptacle outlets required by this section shall be permitted to be located in accordance with municipal, state, federal, or other codes and regulations, or as determined by the designer/building owner.

**Informational Note No. 1:** See Section 314.27(B) for floor boxes used for receptacles located in the floor.

**Informational Note No. 2:** See Article 518 for assembly occupancies designed for 100 or more persons.

---

### Statement of Problem and Substantiation for Public Comment

IEC’s position is to delete 210.71 – (FR 7517)

This is a design issue and there are a variety of ways to provide power in meeting rooms. The NEC cannot make mandatory requirements for receptacle placement in meeting rooms because the configuration of the room can change depending on the needs of a particular meeting. When applying the mandatory rules for receptacle placement in (B), (C) or (D) it is possible to have a meeting room, with a moveable partition, of 1296 square feet to require 16 receptacles. It is also possible to have a meeting room, with a moveable partition, of 2934 square feet to require only 3 receptacles. The mandatory language is unenforceable because of Item (E) and a designer may determine only one receptacle is needed or no receptacles are needed. IEC agrees with the negative ballot comment of Thomas Wood that “this is a design issue that Architects and owners are currently addressing to meet consumer needs”.

210.71 Meeting Rooms.

(A) General.
Each meeting room in other than dwelling units shall have nonlocking-type, 125-volt, 15- and 20-ampere receptacles installed be provided with receptacle outlets. The number and type of receptacle outlets shall be determined in accordance with 210.71(B) through (E). Placement of receptacles shall be in accordance with 210.71(E). Where a room or space is provided with movable partition(s), the room size shall be determined with the partition(s) in the position that results in the smallest size meeting room.

Informational Note No. 1: For the purposes of this section, meeting rooms are typically designed or intended for the gathering of seated occupants for such purposes as conferences, deliberations, or similar purposes, where portable electronic equipment such as computers, projectors, or similar equipment is likely to be used.

Informational Note No. 2: The types of receptacles covered by this requirement are identified as 5-15 and 5-20 in ANSI/NEMA WD 6-2002, National Electrical Manufacturers Association, Standard for Dimensions of Attachment Plugs and Receptacles.

(B) Receptacle Outlets in Fixed Walls.
In meeting rooms having a floor area of 20.93 m² (220.1000 ft²) or less, receptacle outlets shall be installed in accordance with 210.52(A)(1) through (A)(4). These receptacle outlets shall be in addition to any receptacle outlets that are located within cabinets or cupboards, or located more than 1.7 m (5 1/2 ft) above the floor.

(C) Floor Receptacle Outlets.
A meeting room that is at least 3.67 m (12 ft) wide and that has a floor area of at least 21.20 m² (225.215 ft²) and not more than 70.93 m² (760.1000 ft²) shall have at least one duplex- or quadruplex-type receptacle located in the floor at a distance not less than 1.8 m (6 ft) from any fixed wall for each 20 m² (215 ft²) or major portion of floor space.

(D) Receptacle Outlets at Moveable Room Partitions.
At least one floor receptacle outlet shall be installed for each 3.7 linear m (12 linear ft) or major fraction thereof of movable wall measured horizontally along the floor line to serve each meeting room created by the partition. These receptacle outlets shall be located within 450 mm (18 in.) of the partition.

(E) Receptacle Outlet Placement.
In applying the provisions of this section, the total number of receptacle outlets shall not be less than as determined in (B), (C), and (D). The receptacle outlets required by this section shall be permitted to be located in accordance with municipal, state, federal, or other codes and regulations, or as determined by the designer/building owner.

Informational Note No. 1: See Section 314.27(B) for floor boxes used for receptacles located in the floor.

Informational Note No. 2: See Article 518 for assembly occupancies designed for 100 or more persons.

Statement of Problem and Substantiation for Public Comment

The suggested modifications are intended to address the logical negative comments from Mr. Buuck. The proposed changes clarify that Parts (B), (C), and (D) are intended to establish the number and type of receptacle outlets to be installed, and (E) allows the designer/owner to locate those receptacle outlets to best suit the anticipated use of the meeting room. Contrary to some of the comments, there are not an unworkable number of configurations for meeting rooms; they are set up in classroom style, closed “O” or “D”, open ended or horse shoe. In all but the classroom style, electrical power needs are similar for each set-up. This Code addition gives the same design flexibility as found in 210.60.

As was stated by Mr. Woods, designers have recognized the need and are already specifying receptacle outlets in meeting rooms in order to meet the needs of the room users. Most hotel/motel chains and office building owners already have specifications for receptacle outlets, so this requirement will have little impact to those businesses. What it will accomplish is to give the inspection community a means of making sure that there is a minimum number of access points for electrical power in the event that a “value engineered” design might result in an inadequate number of receptacle outlets.

The safety concerns are the same as those in all other locations where a minimum number and type of receptacle outlets are specified in the National Electrical Code: to minimize the use of extension cords and multi-outlet strips that would violate other sections of the Code and the product standards.

Conversions from metric to imperial have been revised where needed, to be consistent with NEC Style Manual Annex C.

NEMA stands on the balance of its substantiation to PI 2872 and urges the Panel to continue to support this revision as modified by this comment.

Committee Statement

Committee Action: Rejected but see related SR
Statement:

Changes were made to 210.71(A) for clarity. The square footage was increased to accommodate a reasonable sized meeting room without including convention halls. These requirements apply to meeting rooms not more than 1000 ft² in area. Informational Note No. 2 was deleted and replaced with a new Informational note to give examples of rooms that are not intended to be meeting rooms.

New 210.71(B) clarifies the number and type of receptacle outlets to be installed. Receptacle outlets in fixed wall and floors are now included in 210.71B(1) and B(2) respectively. These changes also clarify that the building designer or owner is allowed to locate these receptacle outlets to best suit the anticipated use of the meeting room.

Section 210.71(D) for moveable room partitions has been deleted. Section 210.71(E) was also deleted as it is no longer needed.
Public Comment No. 1188-NFPA 70-2015 [Section No. 210.71(D)]

(D) Receptacle Outlets at Moveable Room Partitions.

At least one floor receptacle outlet shall be installed on each side of the moveable room partition, for each 3.7 linear m (12 linear ft) or major fraction thereof of movable wall measured horizontally along the floor line. These receptacle outlets shall be located within 450 mm (18 in.) of the partition.

Statement of Problem and Substantiation for Public Comment

As currently proposed for floor receptacle outlets serving movable room partitions, an installer could install all the required floor receptacles on one side of the partition and meet this proposed Code requirement. This would result in serviceable floor receptacles on one side of a closed room partition and no floor receptacles on the other side, therefore leaving one side of the meeting room space no better off than what we currently have now. If the scenario described above was the intent of the submitter and CMP-2, then ignore this comment. Otherwise, take this public comment as a starting point to address this seemingly inefficiency in this proposed meeting room receptacle outlet requirement, which has merit.

Section 210.71(D) for moveable room partitions has been deleted. Section 210.71(E) was also deleted as it is no longer needed.
Public Comment No. 762-NFPA 70-2015 [Section No. 210.71(D)]

(D) Receptacle Outlets at Moveable Room Partitions.

At least one floor receptacle outlet shall be installed for each 3.7 linear m (12 linear ft) or major fraction thereof of movable wall measured horizontally along the floor line. Where the moveable partition forms two meeting spaces at least one receptacle outlet, meeting the spacing requirements above shall be accessible from both sides of the partition when it is closed. These receptacle outlets shall be located within 450 mm (18 in.) of the partition.

Statement of Problem and Substantiation for Public Comment

Many partitions when closed will form two meeting spaces. If CMP 2 has determined a need to mitigate the use of extension cords (and I agree with such an initiative) it should make sense that this new section should be clear and enforceable in addressing occupancy use on either side of a close partition.

Section 210.71(D) for moveable room partitions has been deleted. Section 210.71(E) was also deleted as it is no longer needed.
(1) General.

Feeder conductors shall have an ampacity not less than required to supply the load as calculated in Parts III, IV, and V of Article 220. Conductors shall be sized to carry not less than the larger of 215.2(A)(1)(a) or (b).

(a) Where a feeder supplies continuous loads or any combination of continuous and noncontinuous loads, the minimum feeder conductor size shall have an allowable ampacity not less than the noncontinuous load plus 125 percent of the continuous load.

Exception No. 1: If the assembly, including the overcurrent devices protecting the feeder(s), is listed for operation at 100 percent of its rating, the allowable ampacity of the feeder conductors shall be permitted to be not less than the sum of the continuous load plus the noncontinuous load.

Exception No. 2: Where a portion of a feeder is connected at both its supply and load ends to separately installed pressure connections as covered in 110.14(C)(2), it shall be permitted to have an allowable ampacity not less than the sum of the continuous load plus the noncontinuous load. No portion of a feeder installed under the provisions of this exception shall extend into an enclosure containing either the feeder supply or the feeder load terminations, as covered in 110.14(C)(1).

Exception No. 3: Grounded conductors that are not connected to an overcurrent device shall be permitted to be sized at 100 percent of the continuous and noncontinuous load.

(b) The minimum feeder conductor size shall have an allowable ampacity, an ampacity, not less than the maximum load to be served after the application of any adjustment or correction factors.

Informational Note No. 1: See Examples D1 through D11 in Informative Annex D.

Informational Note No. 2: Conductors for feeders, as defined in Article 100, sized to prevent a voltage drop exceeding 3 percent at the farthest outlet of power, heating, and lighting loads, or combinations of such loads, and where the maximum total voltage drop on both feeders and branch circuits to the farthest outlet does not exceed 5 percent, will provide reasonable efficiency of operation.

Informational Note No. 3: See 210.19(A), Informational Note No. 4, for voltage drop for branch circuits.

Statement of Problem and Substantiation for Public Comment

I agree with the Panel's statement for PI 1269, that two separate comparisons are required to size the conductor properly. I still maintain that the current text is confusing. I would first ask the Panel if there is a difference between ampacity, which is defined in Article 100, and allowable ampacity which is not. I have asked numerous users of the Code to read the current text of 215.2(A)(1) and describe the difference between allowable ampacity and ampacity. The majority respond that an ampacity is read from a table in 310.15 such as Table 310.15(B)(16), and an allowable ampacity results from considering conditions of use and applying adjustment and correction factors. Although this is incorrect and actually backwards, the language in the text of 215.2(A)(1)(b) of "an allowable ampacity not less than the maximum load to be served after the application of any adjustment or correction factors." leads users of the Code to believe an allowable ampacity results from considering conditions of use. Again, this is incorrect. If ampacity is defined in Article 100 as considering the conditions of use, and an allowable ampacity is from an allowable ampacity table in 310.15 such as Table 310.15(B)(16), how can there be an allowable ampacity after conditions of use? After conditions of use and adjustment and correction factors have been applied, is not the result an ampacity, not an allowable ampacity? The current charging text of 215.2(A)(1) requires the conductor to have an ampacity not less than the maximum load to be served. How is the intent of that statement any different than the intent of 215.2(A)(1)(b)? In 215.2(A)(1)(b), I have removed the word allowable as the current text is technically incorrect and inconsistent with the definition of ampacity and allowable ampacity tables of 310.15 and it is causing confusion. If the panel disagrees, then I ask for the Panel to clarify the two separate comparisons by defining the difference between ampacity and allowable ampacity as used in this section since both terms are used.

(1) General. Feeder conductors shall have an allowable ampacity, after the application of any adjustment or correction factors, not less than required to supply the load as calculated in Parts III, IV, and V of Article 220. Conductors shall be sized to carry not less than the larger of 215.2(A)(1)(a) or (b). Where a feeder supplies continuous loads or any combination of continuous and noncontinuous loads, the minimum feeder conductor size shall have an allowable ampacity, and coordinated with 240.4 for overcurrent protection. Additionally, conductor size shall be coordinated with 110.14(C) temperature limitation under same temperature column of Table 310.15(B)(16) to have an allowable ampacity, without adjustment and correction, not less than the noncontinuous load plus 125 percent of the continuous load.

Exception No. 1: If the assembly, including the overcurrent devices protecting the feeder(s), is listed for operation at 100 percent of its rating, the allowable ampacity of the feeder conductors shall be permitted to be not less than the sum of the continuous load plus the noncontinuous load.

Exception No. 2: Where a portion of a feeder is connected at both its supply and load ends to separately installed pressure connections as covered in 110.14(C)(2), it shall be permitted to have an allowable ampacity not less than the sum of the continuous load plus the noncontinuous load. No portion of a feeder installed under the provisions of this exception shall extend into an enclosure containing either the feeder supply or the feeder load terminations, as covered in 110.14(C)(1).

Exception No. 3: Grounded conductors that are not connected to an overcurrent device shall be permitted to be sized at 100 percent of the continuous and noncontinuous load.

• The minimum feeder conductor size shall have an allowable ampacity not less than the maximum load to be served after the application of any adjustment or correction factors.

Informational Note No. 1: See Examples D1 through D11 in Informative Annex D.

Informational Note No. 2: Conductors for feeders, as defined in Article 100, sized to prevent a voltage drop exceeding 3 percent at the farthest outlet of power, heating, and lighting loads, or combinations of such loads, and where the maximum total voltage drop on both feeders and branch circuits to the farthest outlet does not exceed 5 percent, will provide reasonable efficiency of operation.

Informational Note No. 3: See 210.19(A), Informational Note No. 4, for voltage drop for branch circuits.

Statement of Problem and Substantiation for Public Comment

Through previous editions apprentices and indirectly-related tradespersons have had difficulty understanding how to properly determine the minimum rating and size feeder conductor which meets all the requirements. Such determination requires taking not just this section, but others sections into consideration as well. Proposed wording indicates the other sections which influence this determination and eliminates redundant or excessive wording.

If accepted, wording similar to this should be correlated to other sections using similar wording, e.g. 210.19(A) and 230.42(A).

Committee Statement

Committee Action: Rejected
Resolution: The NEC is intended for use by trained persons. Attempting to incorporate all of the installation rules into each specific application area can create unintended restrictions and potentially not include other requirements that drive the safe installation of the electrical system.
(2) Grounded Conductor.

The size of the feeder circuit grounded conductor shall not be

a. Not smaller than the ungrounded conductors, or

b. Not smaller than that required by 250.122, except that 250.122(F) shall not apply where grounded conductors are run in parallel. If a grounded conductor is sized smaller than the ungrounded conductors, it shall be protected by an Overcurrent Protection Device so that its ampacity is not exceeded under fault conditions of the ungrounded conductors. The Overcurrent Protection device shall open all the ungrounded conductors.

c. Additional minimum sizes shall be as specified in 215.2(A)(3) under the conditions stipulated.

Statement of Problem and Substantiation for Public Comment

As 215.2A@ currently reads, Fault conditions on the ungrounded conductors (for example, single phasing of a 3-phase motor or transformer) can cause a grounded conductor which is downsized (smaller than the ungrounded conductors) to exceed its ampacity, and carry a load equal to that of the remaining ungrounded conductors, possibly causing a fire. This proposed change would prevent that, by sensing the over-current on the grounded conductor, and opening up all the ungrounded conductors. This brings the NEC into conformity with British Standard BS7671 of 2008, 17th edition, where section 524.3 permits downsizing of neutral if (among other conditions) the neutral is protected against overcurrents appropriate to its crosssection area. British Standard BS7671, 17th edition of 2008, Section 431.2.1 says the overcurrent detection on the neutral shall cause the line conductors to be disconnected.

Committee Statement

Committee Action: Rejected
Resolution: The sizing of the grounded conductor is addressed by referencing 250.122 which includes motor circuits. Protection of the grounded conductor is addressed in 240.22 and is outside the scope of CMP-2.
215.9 Ground-Fault Circuit-Interrupter Protection for Personnel. Feeders supplying 15- and 20-ampere receptacle branch circuits shall be permitted to be protected by a ground-fault circuit interrupter or a special-purpose ground-fault circuit interrupter installed in a readily accessible location in lieu of the provisions for such interrupters as specified in 210.8 and 590.6(A).

Statement of Problem and Substantiation for Public Comment

Fatality Statistics continue to show electrocutions as a significant cause of death at the work place. The 2015 NFPA 70E Standard, Annex K states that electrocutions are the fourth leading cause of industrial fatalities. It also stated that the National Safety Council estimates that about 1000 fatalities every year are due to electrocution, where more that 50% of them take place on system voltage less than 600 V. Moreover, approximately 30,000 non-fatal electrical shock accidents occur every year.

UL 943C identifies protective devices designated as special purpose GFCI (SPGFCI) and thus designed to meet the both NEC and NFPA 70E definition of devices intended for personnel protection. Updating the NFPA 70E code to include SPGFCIs designed and approved for industrial applications per UL 943C holds the promise of significantly reducing loss of life at the work place.

Committee Statement
Committee Action: Rejected
Resolution: References to SPGFCI have not been added to Articles 210 and 215.
(2) Feeder Suppliers from Direct-Current Systems.

Where a feeder is supplied from a dc system operating at more than 50–60 volts, each ungrounded conductor of 4 AWG or larger shall be identified by polarity at all termination, connection, and splice points by marking tape, tagging, or other approved means; each ungrounded conductor of 6 AWG or smaller shall be identified by polarity at all termination, connection, and splice points in compliance with 215.12(C)(2)(a) and (b). The identification methods utilized for conductors originating within each feeder panelboard or similar feeder distribution equipment shall be documented in a manner that is readily available or shall be permanently posted at each feeder panelboard or similar feeder distribution equipment.

(a) Positive Polarity, Sizes 6 AWG or Smaller. Where the positive polarity of a dc system does not serve as the connection for the grounded conductor, each positive ungrounded conductor shall be identified by one of the following means:

(2) A continuous red outer finish
(3) A continuous red stripe durably marked along the conductor's entire length on insulation of a color other than green, white, gray, or black
(4) Imprinted plus signs (+)

±

(1) or the word POSITIVE or POS durably marked on insulation of a color other than green, white, gray, or black, and repeated at intervals not exceeding 610 mm (24 in.) in accordance with 310.120(B)

(e) Negative Polarity, Sizes 6 AWG or Smaller. Where the negative polarity of a dc system does not serve as the connection for the grounded conductor, each negative ungrounded conductor shall be identified by one of the following means:

(6) A continuous black outer finish
(7) A continuous black stripe durably marked along the conductor's entire length on insulation of a color other than green, white, gray, or red
(8) Imprinted minus signs (−) or the word NEGATIVE or NEG durably marked on insulation of a color other than green, white, gray, or red, and repeated at intervals not exceeding 610 mm (24 in.) in accordance with 310.120(B)

Statement of Problem and Substantiation for Public Comment

The CMP accepted the proposal, PI-4607, to change the DC voltage from 50V to 60V to align with new Art 712 in 210.5.(C)(2) for branch circuits. It follows that for the same reason 50V should be changed to 60V in 215.12(C)(2) for feeders. Both the feeder and branch voltages should use the same break point voltage and having two different voltages would be a major discrepancy in the NEC.

(8) Imprinted minus signs (–) or the word NEGATIVE or NEG durably marked on insulation of a color other than green, white, gray, or red, and repeated at intervals not exceeding 610 mm (24 in.) in accordance with 310.120(B)

Statement of Problem and Substantiation for Public Comment

Robert Bosch LLC (Bosch) proposes two amendments to Article 215.12(C)(2).

The first amendment changes the 50 volts requirement to 60 volts to align with articles 210.5(C)(2) and 712.

The second amendment clarifies how existing wiring circuits in buildings being converted to a dc system will be identified. The reason for this amendment is that existing ungrounded conductors of 6 AWG or smaller in buildings being converted to a dc system can also be safely reused and identified per the same requirements as ungrounded conductors of 4 AWG or larger without any safety or reliability concerns. It is reasonable for the present requirements for 6 AWG or smaller in Article 215.12(C)(2)(a) and (b) to apply to new building construction, however for existing buildings it would in essence require perfectly usable existing wiring to be removed/disposed of and new wiring to be installed. This adds extra unnecessary waste/cost with the potential to create a less reliable and safe wiring environment through the extensive rework necessary, for zero benefit as the existing wiring does not need replacement and can be properly identified. The retrofit of specific existing wiring circuits to operate on a dc system, such as lighting circuits in commercial buildings, rather than having to install new wiring represents a tremendous improvement in utilization of renewable energy, overall system reliability, and resiliency to power outages with long-term cost effective savings and no impact to safety and reliability. Conversion to DC circuits also offers the opportunity to utilize high-resistance midpoint grounding schemes, which substantially reduces the chances of electric shock, since both current-carrying conductors have a high-resistance path to ground in this configuration.

**Committee Statement**

| Committee Action: Rejected but see related SR |
| Resolution: SR-327-NFPA 70-2015 |
| Statement: A list item has been added to the identification means of positive and negative polarity conductors. This addition supports the re-use of feeder conductors for DC applications. |

Section 215.12(C)(2) is revised to support consistency in moving from 50V to 60V.
Public Comment No. 1378-NFPA 70-2015 [Section No. 215.12(C)(2)]

(2) Feeders Supplied from Direct-Current Systems.

Where a feeder is supplied from a dc system operating at more than 50 volts, each ungrounded conductor of 4 AWG or larger shall be identified by polarity at all termination, connection, and splice points by marking tape, tagging, or other approved means; each ungrounded conductor of 6 AWG or smaller shall be identified by polarity at all termination, connection, and splice points in compliance with 215.12(C)(2)(a) and (b). The identification methods utilized for conductors originating within each feeder panelboard or similar feeder distribution equipment shall be documented in a manner that is readily available or shall be permanently posted at each feeder panelboard or similar feeder distribution equipment.

(a) Positive Polarity, Sizes 6 AWG or Smaller. Where the positive polarity of a dc system does not serve as the connection for the grounded conductor, each positive ungrounded conductor shall be identified by one of the following means:

(2) A continuous red outer finish
(3) A continuous red stripe durably marked along the conductor’s entire length on insulation of a color other than green, white, gray, or black
(4) Imprinted plus signs (+)

±

(1) or the word POSITIVE or POS durably marked on insulation of a color other than green, white, gray, or black, and repeated at intervals not exceeding 610 mm (24 in.) in accordance with 310.120(B)
(2) A permanent listed marking means such as sleeving or shrink-tubing that is suitable for the conductor size, at all termination, connection, and splice points, with imprinted plus signs (+) or the word POSITIVE or POS durably marked on insulation of a color other than green, white, gray, or black. Marking tape shall not be permitted.

(e) Negative Polarity, Sizes 6 AWG or Smaller. Where the negative polarity of a dc system does not serve as the connection for the grounded conductor, each negative ungrounded conductor shall be identified by one of the following means:

(6) A continuous black outer finish
(7) A continuous black stripe durably marked along the conductor’s entire length on insulation of a color other than green, white, gray, or red
(8) Imprinted minus signs (−) or the word NEGATIVE or NEG durably marked on insulation of a color other than green, white, gray, or red, and repeated at intervals not exceeding 610 mm (24 in.) in accordance with 310.120(B)
(9) A permanent listed marking means such as sleeving or shrink-tubing that is suitable for the conductor size, at all termination, connection, and splice points, with imprinted minus signs (−) or the word NEGATIVE or NEG durably marked on insulation of a color other than green white, gray, or red. Marking tape shall not be permitted.

Statement of Problem and Substantiation for Public Comment

215.12(C)(2) was a new requirement in the 2014 NEC. It was a positive step forward in requiring clear identification of dc wiring and its polarity. Looking forward, a large part of the application of dc microgrids (see Article 712) and the LED retrofit business will involve dc power distribution through existing branch circuits. The 2014 Code did not consider this re-use case for marking, and essentially requires new cable to be pulled when a modern permanent marking method such as printed heat shrink sleeves would be quite adequate. This change is proposed in order to support this emerging, environmentally important LED retrofit industry. It allows marking by up to date, permanent means (e.g. heat shrink sleeve), and re-use of branch conductors for dc lighting and dc microgrid applications.

Regarding the safety of re-use of 277 Vac branch circuits and feeders for dc applications, building wire is typically rated for 600V ac and dc. The nominal voltage to ground of most dc microgrids is 190 Vdc (380 V center-resistively grounded). This imparts significantly less stress on insulation than 277 Vac which impresses 277 x root(2) = 390 Vpeak to ground. Ungrounded dc microgrid systems are also required to have ground fault protection by both articles 250 and 712.

Public Comment No. 1454-NFPA 70-2015 [Section No. 215.12(C)(2)]

(2) Feeders Supplied from Direct-Current Systems.

Where a feeder is supplied from a dc system operating at more than 50 volts, each ungrounded conductor of 4 AWG or larger shall be identified by polarity at all termination, connection, and splice points by marking tape, tagging, or other approved means; each ungrounded conductor of 6 AWG or smaller shall be identified by polarity at all termination, connection, and splice points in compliance with 215.12(C)(2)(a) and (b). The identification methods utilized for conductors originating within each feeder panelboard or similar feeder distribution equipment shall be documented in a manner that is readily available or shall be permanently posted at each feeder panelboard or similar feeder distribution equipment.

(a) Positive Polarity, Sizes 6 AWG or Smaller.

Where the positive polarity of a dc system does not serve as the connection for the grounded conductor, each positive ungrounded conductor shall be identified by one of the following means:

(2) A continuous red outer finish

(3) A continuous red stripe durably marked along the conductor’s entire length on insulation of a color other than green, white, gray, or black

(4) Imprinted plus signs (+)

±

(1) or the word POSITIVE or POS durably marked on insulation of a color other than green, white, gray, or black, and repeated at intervals not exceeding 610 mm (24 in.) in accordance with 310.120(B)

(2) In retrofit work, a permanent sleeve or tube marked /POSITIVE/POS at all splices and terminations shall be permitted

(e) Negative Polarity, Sizes 6 AWG or Smaller.

Where the negative polarity of a dc system does not serve as the connection for the grounded conductor, each negative ungrounded conductor shall be identified by one of the following means:

(6) A continuous black outer finish

(7) A continuous black stripe durably marked along the conductor’s entire length on insulation of a color other than green, white, gray, or red

(8) Imprinted minus signs (–) or the word NEGATIVE or NEG durably marked on insulation of a color other than green, white, gray, or red, and repeated at intervals not exceeding 610 mm (24 in.) in accordance with 310.120(B)

(9) In retrofit work, a permanent sleeve or tube marked -/NEGATIVE/NEG at all splices and terminations shall be permitted

Statement of Problem and Substantiation for Public Comment

There is increasing interest in retrofitting DC microgrids into buildings for improved energy efficiency, reliability, and self-generation of power from e.g. solar. The proposed change will provide a safe, permanent means of marking DC circuits without pulling new wire.

(2) Feeders Supplied from Direct-Current Systems.

Where a feeder is supplied from a dc system operating at more than 50 volts, each ungrounded conductor of 4 AWG or larger shall be identified by polarity at all termination, connection, and splice points by marking tape, tagging, or other approved means; each ungrounded conductor of 6 AWG or smaller shall be identified by polarity at all termination, connection, and splice points in compliance with 215.12(C)(2)(a) and (b). The identification methods utilized for conductors originating within each feeder panelboard or similar feeder distribution equipment shall be documented in a manner that is readily available or shall be permanently posted at each feeder panelboard or similar feeder distribution equipment.

(a) Positive Polarity, Sizes 6 AWG or Smaller. Where the positive polarity of a dc system does not serve as the connection for the grounded conductor, each positive ungrounded conductor shall be identified by one of the following means:

(2) A continuous red outer finish

(3) A continuous red stripe durably marked along the conductor’s entire length on insulation of a color other than green, white, gray, or black

(4) Imprinted plus signs (+)

±

(1) or the word POSITIVE or POS durably marked on insulation of a color other than green, white, gray, or black, and repeated at intervals not exceeding 610 mm (24 in.) in accordance with 310.120(B)

(e) Negative Polarity, Sizes 6 AWG or Smaller. Where the negative polarity of a dc system does not serve as the connection for the grounded conductor, each negative ungrounded conductor shall be identified by one of the following means:

(6) A continuous black outer finish

(7) A continuous black stripe durably marked along the conductor’s entire length on insulation of a color other than green, white, gray, or red

(8) Imprinted minus signs (–) or the word NEGATIVE or NEG durably marked on insulation of a color other than green, white, gray, or red, and repeated at intervals not exceeding 610 mm (24 in.) in accordance with 310.120(B)

Exception: In retrofit installations where existing conductors are to be converted to dc, it is permissible to mark only the dc voltage, “dc,” and polarity at each termination, connection, and splice point in compliance with 215.12(C)(1)(a) and (b).

Statement of Problem and Substantiation for Public Comment

The Code requires continuous identification of ungrounded dc feeders via markings every 24”. This puts undue financial burden on retrofit installations.

The EMerge Alliance proposes to allow the re-use of existing conductors in retrofit situations through suitable marking means as accepted elsewhere in the Code.

We do not believe there will be any adverse safety risk caused by this change.

The previously accepted exception to 210.5(C)1 in FR 302 above should apply to 215.12(C)2, with suitable contextual wording changes.

### Statement of Problem and Substantiation for Public Comment

Section 220.3 was revised to clarify the application of the table and for consistency with the title of Table 210.3.

Other than for listing requirements not amended by Chapters 5, 6 & 7, Table 220.3 is not necessary nor is it all inclusive as it exists. Section 90.3 already provides the guidance that specific equipment and applications in Chapters 5, 6 & 7 can amend or supplement the calculations in Article 220 so the sections referencing calculations in those Chapters can be removed.

Tables such as this are helpful and benefit readers when they remain all inclusive. However, it would be a challenging task to provide readers with a continually updated list of all the sections that include calculations that amend or supplement those in Article 220 so only the references that do not amend or supplement those in Article 220 via 90.3 were kept.

Committee Statement

Committee Action: Accepted
Resolution: SR-312-NFPA 70-2015
Statement: Section 220.3 is revised to clarify the application of the table. Other than for listing specific purpose requirements in Chapters 2, 3 & 4, Table 220.3 is not necessary nor is it all inclusive as it exists. Section 90.3 already provides the guidance that specific equipment and applications in Chapters 5, 6 & 7 can amend or supplement the feeder requirements in Article 220, so the sections referencing feeder requirements in those chapters can been removed.

National Fire Protection Association Report http://submittals.nfpa.org/TerraViewWeb/ContentFetcher?commentPara...
220.12 Lighting Load for Specified Occupancies.

A unit load of not less than that specified in Table 220.12 for occupancies specified shall constitute the minimum lighting load. The floor area for each floor shall be calculated from the outside dimensions of the building, dwelling unit, or other area involved. For dwelling units, the calculated floor area shall not include open porches, garages, or unused or unfinished spaces not adaptable for future use.

Informational Note: The unit values are based on minimum load conditions and 100 percent power factor and may not provide sufficient capacity for the installation contemplated.

Exception No. 1: Where the building is designed and constructed to comply with an energy code adopted by the local authority, the lighting load shall be permitted to be calculated at the values specified in the energy code where the following conditions are met:

(1) A power monitoring system is installed that will provide continuous information regarding the total general lighting load of the building.

(2) The power monitoring system will be set with alarm values to alert the building owner or manager if the lighting load exceeds the values set by the energy code.

(3) The demand factors specified in 220.42 are not applied to the general lighting load.

Exception No. 2: Where an building is entirely an office or a bank type occupancy and the lighting is designed and constructed to comply with an energy code adopted by the local authority with a lighting density of less than 13.5 Volt-Amperes/Square Meter (1 Volt-Amperes/Square Foot), the unit lighting load for those type occupancies in Table 220.12 shall be permitted to be reduced by 11 Volt-Amperes/Square Meter (1 Volt-Ampers/Square Foot).

Statement of Problem and Substantiation for Public Comment

The typical light fixture of choice to provide illumination for office buildings, banks, and most other occupancies is the 2’x4 Lay-in Troffer. In the late 1980’s this fixture provide illumination with 4 fluorescent lamps using an electromagnetic ballast. The wattage for this fixture was approximately 180 watts. This fixture was normally installed on 8’ by 10’ centers or 1 fixture for every 80 square feet of office space. This equated out to a lighting power density of 2.2 watts per square foot. If you move ahead into the mid to late 1990’s the original T-12 lamps of the 1980’s were being replaced with T-8 and electronic ballasts. The same 2x4 Fluorescent fixture with T-8 lamps now required only 110 watts of power. Using the same standard fluorescent light fixture placement of 1 fixture for every 80 square feet the lighting power density was reduced to 1.375 watts per square foot.

Fast forwarding to the last few years two things have happened. First, the original 1980’s illumination standards of 70 footcandles has been reduced downward to 40 to 50 footcandles. Studies have been shown that with the advent of the computer screen and for other reasons the original illumination level was outdated. Second the invention of LED’s has driven wattage down again. An equivalent 2’x4’ LED fixture that would produce the same lumen output as a 4 lamp T-8 Troffer now draws 71 watts. With the same 80 square foot per fixture we are now down to .8875 watts per square foot. If you take into account the reduced lighting levels of 40 to 50 footcandles lighting designers are no longer installing 4 lamps fluorescents but are moving to 2 or 3 lamps fixture to achieve the lower light levels. LED 2’x4 fixtures with equivalent lumen output of 2 to 3 lamps are around 38 watts per fixture or .475 watts per square foot.

The reduction in lighting power is also a result of Nationally Recognized Energy standards such as ASHRAE and IECC. These documents, where adopted, have steadily mandated lower and lower lighting power densities in various occupancy types across the country. While the adoption of these standards was sparse 10 to 15 years ago, in today’s world they are commonplace. In the 2013 version of ASHRAE, the lighting power densities for office type buildings is mandated to be less than .82 watts per square foot.

I have attached excerpts from both the ASHRAE and IECC lighting power allowance standards to show the required allowances if a building department or AHJ requires these standards to be adopted. We are seeking relief on the decades old lighting power allowance of 3.5 watts per square foot for offices and banks. We are asking that this value be reduced to 2.5 watts per square foot for office or bank type occupancies where it can be shown that the building is designed based on a Nationally recognized lighting power density of 1.2 watts per square foot or less. We this this is a safe value based upon the standards in place and are providing a 200% safety factor.

We also think that this is a safety issue. By reducing the lighting allowance we are allowing services to be reduced in size which will in turn reduce the size of the main overcurrent device. Utilities, when calculating their demand for their system, already take into account the reduced lighting load and size their system accordingly. Installing smaller transformer provides a lower fault current level but installing large breakers that are mandated by NEC sizing rules facilitates the possibility for larger incident energy values.

We have attached portions of Table 9.6.1 from a ASHRAE 2013 Energy standard that shows a lighting power density for banking areas at 1.01 watts per square foot and also attached Table 9.5.1 which shows a lighting power density for offices at .82 watts per square foot.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-313-NFPA 70-2015
Statement: The new exception establishes the path by which the energy code will reduce the lighting load to a level of 2.5VA / sq. ft. for office and bank areas.
Public Comment No. 125-NFPA 70-2015 [Article 225]

Article 225. Outside Branch Circuits and Feeders

225.1 Scope.

This article covers requirements for outside branch circuits and feeders run on or between buildings, structures, or poles on the premises; and electrical equipment and wiring for the supply of utilization equipment that is located on or attached to the outside of buildings, structures, or poles.

Informational Note: For additional information on wiring over 1000 volts, see ANSI C2-2007, National Electrical Safety Code.

225.3 Other Articles.

Application of other articles, including additional requirements to specific cases of equipment and conductors, is shown in Table 225.3.

Part I. General

225.4 Conductor Covering.

Where within 3.0 m (10 ft) of any building or structure other than supporting poles or towers, open individual (aerial) overhead conductors shall be insulated for the nominal voltage. The insulation of conductors in cables or raceways, except Type MI cable, shall be of thermoset or thermoplastic type and, in wet locations, shall comply with 310.10(C). The insulation of conductors for festoon lighting shall be of the rubber-covered or thermoplastic type.

Exception: Equipment grounding conductors and grounded circuit conductors shall be permitted to be bare or covered as specifically permitted elsewhere in this Code.

225.5 Size of Conductors 600 Volts, Nominal, or Less.

The ampacity of outdoor branch-circuit and feeder conductors shall be in accordance with 310.15 based on loads as determined under 220.10 and Part III of Article 220.

225.6 Conductor Size and Support.
Overhead Spans.

Open individual conductors shall not be smaller than the following:

1. For 1000 volts, nominal, or less, 10 AWG copper or 8 AWG aluminum for spans up to 15 m (50 ft) in length, and 8 AWG copper or 6 AWG aluminum for a longer span unless supported by a messenger wire.

2. For over 1000 volts, nominal, 6 AWG copper or 4 AWG aluminum where open individual conductors, and 8 AWG copper or 6 AWG aluminum where in cable.

Festoon Lighting.

Overhead conductors for festoon lighting shall not be smaller than 12 AWG unless the conductors are supported by messenger wires. In all spans exceeding 12 m (40 ft), the conductors shall be supported by messenger wire. The messenger wire shall be supported by strain insulators. Conductors or messenger wires shall not be attached to any fire escape, downspout, or plumbing equipment.

Lighting Equipment Installed Outdoors.

(A) General.

For the supply of lighting equipment installed outdoors, the branch circuits shall comply with Article 210 and 225.7(B) through (D).

(B) Common Neutral.

The ampacity of the neutral conductor shall not be less than the maximum net calculated load current between the neutral conductor and all ungrounded conductors connected to any one phase of the circuit.

(C) 277 Volts to Ground.

Circuits exceeding 120 volts, nominal, between conductors and not exceeding 277 volts, nominal, to ground shall be permitted to supply luminaires for illumination of outdoor areas of industrial establishments, office buildings, schools, stores, and other commercial or public buildings.

(D) 1000 Volts Between Conductors.

Circuits exceeding 277 volts, nominal, to ground and not exceeding 1000 volts, nominal, between conductors shall be permitted to supply the auxiliary equipment of electric-discharge lamps in accordance with 210.6(D) (1).

Calculation of Loads 1000 Volts, Nominal, or Less.

(A) Branch Circuits.

The load on outdoor branch circuits shall be as determined by 220.10.

(B) Feeders.

The load on outdoor feeders shall be as determined by Part III of Article 220.
225.10  Wiring on Buildings (or Other Structures).
The installation of outside wiring on surfaces of buildings (or other structures) shall be permitted for circuits of not over 1000 volts, nominal, as the following:

(1) Auxiliary gutters
(2) Busways
(3) Cable trays
(4) Cablebus
(5) Electrical metallic tubing (EMT)
(6) Flexible metal conduit (FMC)
(7) Intermediate metal conduit (IMC)
(8) Liquidtight flexible metal conduit (LFMC)
(9) Liquidtight flexible nonmetallic conduit (LFNC)
(10) Messenger-supported wiring
(11) Multiconductor cable
(12) Open wiring on insulators
(13) Reinforced thermosetting resin conduit (RTRC)
(14) Rigid metal conduit (RMC)
(15) Rigid polyvinyl chloride conduit (PVC)
(16) Type MC cable
(17) Type MI cable
(18) Type UF cable
(19) Wireways

Circuits of over 1000 volts, nominal, shall be installed as provided in 300.37.

225.11  Feeder and Branch-Circuit Conductors Entering, Exiting, or Attached to Buildings or Structures.
Feeder and branch-circuit conductors entering or exiting buildings or structures shall be installed in accordance with the requirements of 230.52. Overhead branch circuits and feeders attached to buildings or structures shall be installed in accordance with the requirements of 230.54.

225.12  Open-Conductor Supports.
Open conductors shall be supported on knobs, racks, brackets, or strain insulators, that are made of glass, porcelain, or other approved materials.

225.14  Open-Conductor Spacings.
(A)  1000 Volts, Nominal, or Less.
Conductors of 1000 volts, nominal, or less, shall comply with the spacings provided in Table 230.51(C).

(B)  Over 1000 Volts, Nominal.
Conductors of over 1000 volts, nominal, shall comply with the spacings provided in 110.36 and 490.24.

(C)  Separation from Other Circuits.
Open conductors shall be separated from open conductors of other circuits or systems by not less than 100 mm (4 in.).

(D)  Conductors on Poles.
Conductors on poles shall have a separation of not less than 300 mm (1 ft) where not placed on racks or brackets. Conductors supported on poles shall provide a horizontal climbing space not less than the following:

(1) Power conductors below communications conductors — 750 mm (30 in.)
(2) Power conductors alone or above communications conductors:
   (3)  300 volts or less — 600 mm (24 in.)
   (4)  Over 300 volts — 750 mm (30 in.)

(5) Communications conductors below power conductors — same as power conductors
(6) Communications conductors alone — no requirement

225.15  Supports over Buildings.
Supports over a building shall be in accordance with 230.29.

225.16  Attachment to Buildings.
(A) Point of Attachment.

The point of attachment to a building shall be in accordance with 230.26.

(B) Means of Attachment.

The means of attachment to a building shall be in accordance with 230.27.

225.17 Masts as Supports.

Only feeder or branch-circuit conductors specified within this section shall be permitted to be attached to the feeder and/or branch-circuit mast. Masts used for the support of final spans of feeders or branch circuits shall be installed in accordance with 225.17(A) and (B).

(A) Strength.

The mast shall have adequate strength or be supported by braces or guys to safely withstand the strain imposed by the overhead feeder or branch-circuit conductors. Hubs intended for use with a conduit serving as a mast for support of feeder or branch-circuit conductors shall be identified for use with a mast.

(B) Attachment.

Feeder and/or branch-circuit conductors shall not be attached to a mast where the connection is between a weatherhead or the end of the conduit and a coupling where the coupling is located above the last point of securement to the building or other structure, or where the coupling is located above the building or other structure.

225.18 Clearance for Overhead Conductors and Cables.

Overhead spans of open conductors and open multicore cables of not over 1000 volts, nominal, shall have a clearance of not less than the following:

1. 3.0 m (10 ft) — above finished grade, sidewalks, or from any platform or projection from which they are reachable where the voltage does not exceed 150 volts to ground and accessible to pedestrians only.

2. 3.7 m (12 ft) — over residential property and driveways, and those commercial areas not subject to truck traffic where the voltage does not exceed 300 volts to ground.

3. 4.5 m (15 ft) — for those areas listed in the 3.7 m (12 ft) classification where the voltage exceeds 300 volts to ground.

4. 5.5 m (18 ft) — over public streets, alleys, roads, parking areas subject to truck traffic, driveways on other than residential property, and other land traversed by vehicles, such as cultivated, grazing, forest, and orchard.

5. 7.5 m (24 1/2 ft) — over track rails of railroads.

225.19 Clearances from Buildings for Conductors of Not over 1000 Volts, Nominal.

(A) Above Roofs.

Overhead spans of open conductors and open multicore cables shall have a vertical clearance of not less than 2.7 m (8 ft 6 in.) above the roof surface. The vertical clearance above the roof level shall be maintained for a distance not less than 900 mm (3 ft) in all directions from the edge of the roof.

Exception No. 1: The area above a roof surface subject to pedestrian or vehicular traffic shall have a vertical clearance from the roof surface in accordance with the clearance requirements of 225.18.

Exception No. 2: Where the voltage between conductors does not exceed 300, and the roof has a slope of 100 mm in 300 mm (4 in. in 12 in.) or greater, a reduction in clearance to 900 mm (3 ft) shall be permitted.

Exception No. 3: Where the voltage between conductors does not exceed 300, a reduction in clearance above only the overhanging portion of the roof to not less than 450 mm (18 in.) shall be permitted if (1) not more than 1.8 m (6 ft) of the conductors, 1.2 m (4 ft) horizontally, pass above the roof overhang, and (2) they are terminated at a through-the-roof raceway or approved support.

Exception No. 4: The requirement for maintaining the vertical clearance 900 mm (3 ft) from the edge of the roof shall not apply to the final conductor span where the conductors are attached to the side of a building.

(B) From Nonbuilding or Nonbridge Structures.

From signs, chimneys, radio and television antennas, tanks, and other nonbuilding or nonbridge structures, clearances — vertical, diagonal, and horizontal — shall not be less than 900 mm (3 ft).

(C) Horizontal Clearances.

Clearances shall not be less than 900 mm (3 ft).

(D) Final Spans.

Final spans of feeders or branch circuits shall comply with 225.19(D)(1), (D)(2), and (D)(3).

1. Clearance from Windows.

Final spans to the building they supply, or from which they are fed, shall be permitted to be attached to the building, but they shall be kept not less than 900 mm (3 ft) from windows that are designed to be opened, and from doors, porches, balconies, ladders, stairs, fire escapes, or similar locations.

Exception: Conductors run above the top level of a window shall be permitted to be less than the 900 mm (3 ft) requirement.
(2) Vertical Clearance.

The vertical clearance of final spans above or within 900 mm (3 ft) measured horizontally of platforms, projections, or surfaces from which they are reachable shall be maintained in accordance with 225.18.

(3) Building Openings.

The overhead branch-circuit and feeder conductors shall not be installed beneath openings through which materials may be moved, such as openings in farm and commercial buildings, and shall not be installed where they obstruct entrance to these openings.

(E) Zone for Fire Ladders.

Where buildings exceed three stories or 15 m (50 ft) in height, overhead lines shall be arranged, where practicable, so that a clear space (or zone) at least 1.8 m (6 ft) wide will be left either adjacent to the buildings or beginning not over 2.5 m (8 ft) from them to facilitate the raising of ladders when necessary for fire fighting.

225.20 Protection Against Physical Damage.

Conductors installed on buildings, structures, or poles shall be protected against physical damage as provided for services in 230.50.

225.21 Multiconductor Cables on Exterior Surfaces of Buildings (or Other Structures).

Supports for multiconductor cables on exterior surfaces of buildings (or other structures) shall be as provided in 230.51.

225.22 Raceways on Exterior Surfaces of Buildings or Other Structures.

Raceways on exteriors of buildings or other structures shall be arranged to drain and shall be listed or approved for use in wet locations.

225.24 Outdoor Lampholders.

Where outdoor lampholders are attached as pendants, the connections to the circuit wires shall be staggered. Where such lampholders have terminals of a type that puncture the insulation and make contact with the conductors, they shall be attached only to conductors of the stranded type.

225.25 Location of Outdoor Lamps.

Locations of lamps for outdoor lighting shall be below all energized conductors, transformers, or other electric utilization equipment, unless either of the following apply:

(1) Clearances or other safeguards are provided for relamping operations.

(2) Equipment is controlled by a disconnecting means that is lockable in accordance with 110.25.

225.26 Vegetation as Support.

Vegetation such as trees shall not be used for support of overhead conductor spans.

225.27 Raceway Seal.

Where a raceway enters a building or structure from outside, it shall be sealed. Spare or unused raceways shall also be sealed. Sealants shall be identified for use with cable insulation, conductor insulation, bare conductor, shield, or other components.

Part II. Buildings or Other Structures Supplied by a Feeder(s) or Branch Circuit(s)

225.30 Number of Supplies.

A building or other structure that is served by a branch circuit or feeder on the load side of a service disconnecting means shall be supplied by only one feeder or branch circuit unless permitted in 225.30(A) through (F). For the purpose of this section, a multiwire branch circuit shall be considered a single circuit.

Where a branch circuit or feeder originates in these additional buildings or other structures, only one feeder or branch circuit shall be permitted to supply power back to the original building or structure, unless permitted in 225.30(A) through (F).

(A) Special Conditions.

Additional feeders or branch circuits shall be permitted to supply the following:

(1) Fire pumps

(2) Emergency systems

(3) Legally required standby systems

(4) Optional standby systems

(5) Parallel power production systems

(6) Systems designed for connection to multiple sources of supply for the purpose of enhanced reliability

(7) Electric vehicle charging systems listed, labeled, and identified for more than a single branch circuit/feeder
Special Occupancies.
By special permission, additional feeders or branch circuits shall be permitted for either of the following:

1. Multiple-occupancy buildings where there is no space available for supply equipment accessible to all occupants
2. A single building or other structure sufficiently large to make two or more supplies necessary

Capacity Requirements.
Additional feeders or branch circuits shall be permitted where the capacity requirements are in excess of 2000 amperes at a supply voltage of 1000 volts or less.

Different Characteristics.
Additional feeders or branch circuits shall be permitted for different voltages, frequencies, or phases, or for different uses such as control of outside lighting from multiple locations.

Documented Switching Procedures.
Additional feeders or branch circuits shall be permitted to supply installations under single management where documented safe switching procedures are established and maintained for disconnection.

One- or Two-Family Dwelling Unit(s).
For a one- or two-family dwelling unit(s) with multiple feeders, it shall be permissible to install not more than six disconnects grouped at one location where the feeders enter the building, provided the feeder conductors are sized 1/0 or larger and originate at the same location.

Disconnecting Means.
Means shall be provided for disconnecting all ungrounded conductors that supply or pass through the building or structure.

Location.
The disconnecting means shall be installed either inside or outside of the building or structure served or where the conductors pass through the building or structure. The disconnecting means shall be at a readily accessible location nearest the point of entrance of the conductors. For the purposes of this section, the requirements in 230.6 shall be utilized.

Exception No. 1: For installations under single management, where documented safe switching procedures are established and maintained for disconnection, and where the installation is monitored by qualified individuals, the disconnecting means shall be permitted to be located elsewhere on the premises.

Exception No. 2: For buildings or other structures qualifying under the provisions of Article 685, the disconnecting means shall be permitted to be located elsewhere on the premises.

Exception No. 3: For towers or poles used as lighting standards, the disconnecting means shall be permitted to be located elsewhere on the premises.

Exception No. 4: For poles or similar structures used only for support of signs installed in accordance with Article 600, the disconnecting means shall be permitted to be located elsewhere on the premises.

Exception No. 5: For electric vehicle charging systems, the disconnecting means shall be installed in accordance with 625.42.

Maximum Number of Disconnects.
(A) General.
The disconnecting means for each supply permitted by 225.30 shall consist of not more than six switches or six circuit breakers mounted in a single enclosure, in a group of separate enclosures, or in or on a switchboard or switchgear. There shall be no more than six disconnects per supply grouped in any one location.

Exception: For the purposes of this section, disconnecting means used solely for the control circuit of the ground-fault protection system, or the control circuit of the power-operated supply disconnecting means, installed as part of the listed equipment, shall not be considered a supply disconnecting means.

(B) Single-Pole Units.
Two or three single-pole switches or breakers capable of individual operation shall be permitted on multwire circuits, one pole for each ungrounded conductor, as one multipole disconnect, provided they are equipped with identified handle ties or a master handle to disconnect all ungrounded conductors with no more than six operations of the hand.

Grouping of Disconnects.
(A) General.
The two to six disconnects as permitted in 225.33 shall be grouped. Each disconnect shall be marked to indicate the load served.

Exception: One of the two to six disconnecting means permitted in 225.33, where used only for a water pump also intended to provide fire protection, shall be permitted to be located remote from the other disconnecting means.

(B) Additional Disconnecting Means.
The one or more additional disconnecting means for fire pumps or for emergency, legally required standby or optional standby system permitted by 225.30 shall be installed sufficiently remote from the one to six disconnecting means for normal supply to minimize the possibility of simultaneous interruption of supply.
225.35  Access to Occupants.

In a multiple-occupancy building, each occupant shall have access to the occupant's supply disconnecting means.

*Exception: In a multiple-occupancy building where electric supply and electrical maintenance are provided by the building management and where these are under continuous building management supervision, the supply disconnecting means supplying more than one occupancy shall be permitted to be accessible to authorized management personnel only.*

225.36  Type of Disconnecting Means.

The disconnecting means specified in 225.31 shall be comprised of a circuit breaker, molded case switch, general-use switch, snap switch, or other approved means. Where applied in accordance with 250.32(B), Exception No. 1, the disconnecting means shall be suitable for use as service equipment.

225.37  Identification.

Where a building or structure has any combination of feeders, branch circuits, or services passing through it or supplying it, a permanent plaque or directory shall be installed at each feeder and branch-circuit disconnect location denoting all other services, feeders, or branch circuits supplying that building or structure or passing through that building or structure and the area served by each.

*Exception No. 1: A plaque or directory shall not be required for large-capacity multibuilding industrial installations under single management, where it is ensured that disconnection can be accomplished by establishing and maintaining safe switching procedures.*

*Exception No. 2: This identification shall not be required for branch circuits installed from a dwelling unit to a second building or structure.*

225.38  Disconnect Construction.

Disconnecting means shall meet the requirements of 225.38(A) through (D).

(A)  Manually or Power Operable.

The disconnecting means shall consist of either (1) a manually operable switch or a circuit breaker equipped with a handle or other suitable operating means or (2) a power-operable switch or circuit breaker, provided the switch or circuit breaker can be opened by hand in the event of a power failure.

(B)  Simultaneous Opening of Poles.

Each building or structure disconnecting means shall simultaneously disconnect all ungrounded supply conductors that it controls from the building or structure wiring system.

(C)  Disconnection of Grounded Conductor.

Where the building or structure disconnecting means does not disconnect the grounded conductor from the grounded conductors in the building or structure wiring, other means shall be provided for this purpose at the location of the disconnecting means. A terminal or bus to which all grounded conductors can be attached by means of pressure connectors shall be permitted for this purpose.

In a multisection switchboard or switchgear, disconnects for the grounded conductor shall be permitted to be in any section of the switchboard or switchgear, if the switchboard section or switchgear section is marked to indicate a grounded conductor disconnect is located within.

(D)  Indicating.

The building or structure disconnecting means shall plainly indicate whether it is in the open or closed position.

225.39  Rating of Disconnect.

The feeder or branch-circuit disconnecting means shall have a rating of not less than the calculated load to be supplied, determined in accordance with Parts I and II of Article 220 for branch circuits, Part III or IV of Article 220 for feeders, or Part V of Article 220 for farm loads. Where the branch circuit or feeder disconnecting means consists of more than one switch or circuit breaker, as permitted by 225.33, combining the ratings of all the switches or circuit breakers for determining the rating of the disconnecting means shall be permitted. In no case shall the rating be lower than specified in 225.39(A), (B), (C), or (D).

(A)  One-Circuit Installation.

For installations to supply only limited loads of a single branch circuit, the branch circuit disconnecting means shall have a rating of not less than 15 amperes.

(B)  Two-Circuit Installations.

For installations consisting of not more than two 2-wire branch circuits, the feeder or branch-circuit disconnecting means shall have a rating of not less than 30 amperes.

(C)  One-Family Dwelling.

For a one-family dwelling, the feeder disconnecting means shall have a rating of not less than 100 amperes, 3-wire.

(D)  All Others.

For all other installations, the feeder or branch-circuit disconnecting means shall have a rating of not less than 60 amperes.

225.40  Access to Overcurrent Protective Devices.

Where a feeder overcurrent device is not readily accessible, branch-circuit overcurrent devices shall be installed on the load side, shall be mounted in a readily accessible location, and shall be of a lower ampere rating than the feeder overcurrent device.
Part III. Over 1000 Volts.

225.50 Sizing of Conductors.

The sizing of conductors over 1000 volts shall be in accordance with 210.19(B) for branch circuits and 215.2(B) for feeders.

225.51 Isolating Switches.

Where oil switches or air, oil, vacuum, or sulfur hexafluoride circuit breakers constitute a building disconnecting means, an isolating switch with visible break contacts and meeting the requirements of 230.204(B), (C), and (D) shall be installed on the supply side of the disconnecting means and all associated equipment.

Exception: The isolating switch shall not be required where the disconnecting means is mounted on removable truck panels or switchgear units that cannot be opened unless the circuit is disconnected and that, when removed from the normal operating position, automatically disconnect the circuit breaker or switch from all energized parts.

225.52 Disconnecting Means.

(A) Location.

A building or structure disconnecting means shall be located in accordance with 225.32, or, if not readily accessible, it shall be operable by mechanical linkage from a readily accessible point. For multibuilding industrial installations under single management, it shall be permitted to be electrically operated by a readily accessible, remote-control device in a separate building or structure.

(B) Type.

Each building or structure disconnect shall simultaneously disconnect all ungrounded supply conductors it controls and shall have a fault-closing rating not less than the maximum available short-circuit current available at its supply terminals.

Exception: Where the individual disconnecting means consists of fused cutouts, the simultaneous disconnection of all ungrounded supply conductors shall not be required if there is a means to disconnect the load before opening the cutouts. A permanent legible sign shall be installed adjacent to the fused cutouts and shall read DISCONNECT LOAD BEFORE OPENING CUTOUTS.

Where fused switches or separately mounted fuses are installed, the fuse characteristics shall be permitted to contribute to the fault closing rating of the disconnecting means.

(C) Locking.

Disconnecting means shall be lockable in accordance with 110.25.

Exception: Where an individual disconnecting means consists of fused cutouts, a suitable enclosure capable of being locked and sized to contain all cutout fuse holders shall be installed at a convenient location to the fused cutouts.

(D) Indicating.

Disconnecting means shall clearly indicate whether they are in the open “off” or closed “on” position.

(E) Uniform Position.

Where disconnecting means handles are operated vertically, the “up” position of the handle shall be the “on” position.

Exception: A switching device having more than one “on” position, such as a double throw switch, shall not be required to comply with this requirement.

(F) Identification.

Where a building or structure has any combination of feeders, branch circuits, or services passing through or supplying it, a permanent plaque or directory shall be installed at each feeder and branch-circuit disconnect location that denotes all other services, feeders, or branch circuits supplying that building or structure or passing through that building or structure and the area served by each.

225.56 Inspections and Tests.

(A) Pre-Energization and Operating Tests.

The complete electrical system design, including settings for protective, switching, and control circuits, shall be prepared in advance and made available on request to the authority having jurisdiction and shall be performance tested when first installed on-site. Each protective, switching, and control circuit shall be adjusted in accordance with the system design and tested by actual operation using current injection or equivalent methods as necessary to ensure that each and every such circuit operates correctly to the satisfaction of the authority having jurisdiction.

(1) Instrument Transformers.

All instrument transformers shall be tested to verify correct polarity and burden.

(2) Protective Relays.

Each protective relay shall be demonstrated to operate by injecting current or voltage, or both, at the associated instrument transformer output terminal and observing that the associated switching and signaling functions occur correctly and in proper time and sequence to accomplish the protective function intended.

(3) Switching Circuits.

Each switching circuit shall be observed to operate the associated equipment being switched.
(4) Control and Signal Circuits.
Each control or signal circuit shall be observed to perform its proper control function or produce a correct signal output.

(5) Metering Circuits.
All metering circuits shall be verified to operate correctly from voltage and current sources in a similar manner to protective relay circuits.

(6) Acceptance Tests.
Complete acceptance tests shall be performed, after the substation installation is completed, on all assemblies, equipment, conductors, and control and protective systems, as applicable, to verify the integrity of all the systems.

(7) Relays and Metering Utilizing Phase Differences.
All relays and metering that use phase differences for operation shall be verified by measuring phase angles at the relay under actual load conditions after operation commences.

(B) Test Report.
A test report covering the results of the tests required in 225.56(A) shall be delivered to the authority having jurisdiction prior to energization.

225.60 Clearances over Roadways, Walkways, Rail, Water, and Open Land.

(A) 22 kV, Nominal, to Ground or Less.
The clearances over roadways, walkways, rail, water, and open land for conductors and live parts up to 22 kV, nominal, to ground or less shall be not less than the values shown in Table 225.60.

(B) Over 22 kV Nominal to Ground.
Clearances for the categories shown in Table 225.60 shall be increased by 10 mm (0.4 in.) per kV above 22,000 volts.

(C) Special Cases.
For special cases, such as where crossings will be made over lakes, rivers, or areas using large vehicles such as mining operations, specific designs shall be engineered considering the special circumstances and shall be approved by the authority having jurisdiction.

Informational Note: For additional information, see ANSI, see IEEE C2-2007, National Electrical Safety Code.

225.10  Wiring on Buildings (or Other Structures).

The installation of outside wiring on surfaces of buildings (or other structures) shall be permitted for circuits of not over 1000 volts, nominal, as the following:

(1) Auxiliary gutters
(2) Busways
(3) Cable trays
(4) Cablebus
(5) Electrical metallic tubing (EMT)
(6) Flexible metal conduit (FMC)
(7) Intermediate metal conduit (IMC)
(8) Liquidtight flexible metal conduit (LFMC)
(9) Liquidtight flexible nonmetallic conduit (LFNC)
(10) Messenger-supported wiring
(11) Multiconductor cable
(12) Open wiring on insulators
(13) Reinforced thermosetting resin conduit (RTRC)
(14) Rigid metal conduit (RMC)
(15) Rigid polyvinyl chloride conduit (PVC)
(16) Type MC cable
(17) Type MI cable
(18) Type UF cable
(19) Wireways

Circuits of over 1000 volts, nominal, shall be installed as provided in 300.37.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs the panel to reconsider the action on FR 1023 relative to the use of the phrase “of over 1000 volts” and consider the use of the preferred phrase “exceeding 1000 volts” to comply with the NEC Style Manual.

225.18 Clearance for Overhead Conductors and Cables.

Overhead spans of open conductors and open multiconductor cables of not over 1000 volts, nominal, shall have a clearance of not less than the following:

1. 3.0 m (10 ft) — above finished grade, sidewalks, or from any platform or projection from which they are reachable platforms or projections, where the voltage does not exceed 150 volts to ground and accessible to pedestrians only

2. 3.7 m (12 ft) — over residential property and driveways, and those commercial areas not subject to truck traffic where the voltage does not exceed 300 volts to ground

3. 4.5 m (15 ft) — for those areas listed in the 3.7 m (12 ft) classification where the voltage exceeds 300 volts to ground

4. 5.5 m (18 ft) — over public streets, alleys, roads, parking areas subject to truck traffic, driveways on other than residential property, and other land traversed by vehicles, such as cultivated, grazing, forest, and orchard

5. 7.5 m (24 1/2 ft) — over track rails of railroads

Statement of Problem and Substantiation for Public Comment

Proposed wording is awkward, at best. I believe the thought can be accurately conveyed using less words. And, I couldn't find 'reachable' in the dictionary.

### Public Comment No. 332-NFPA 70-2015 [Section No. 225.22]

**225.22 Raceways on Exterior Surfaces of Buildings or Other Structures.**
Raceways on exteriors of buildings or other structures shall be arranged to drain and shall be listed or approved (listed) for use in wet locations.

### Statement of Problem and Substantiation for Public Comment

All of the raceway articles require the use of listed raceways. The use of the words "or approved" add confusion as they suggest that the use of a raceway that is not listed would be permitted in a wet location.

**State:**  
**Zip:**  
**Submittal Date:** Fri Jul 31 17:17:40 EDT 2015

### Committee Statement

**Committee Action:** Rejected  
**Resolution:** The word “Approved” is intended to be used here. The submitter is correct in that the various raceway articles use language relative to listing. The reason the word approved is used here is that there are times when custom raceways are built on site that are not covered by this code and that also do not bear listing marks. In these special cases it is intended that the AHJ has the ability to approve the use of such raceways.
Public Comment No. 1134-NFPA 70-2015 [Section No. 225.27]

225.27 Raceway Seal.
Where a raceway enters a building or structure from outside an underground distribution system, it shall be sealed in accordance with 300.5(G). Spare or unused raceways shall also be sealed. Sealants shall be identified for use with cable insulation, conductor insulation, bare conductor, shield, or and other components.

Statement of Problem and Substantiation for Public Comment

Requiring that all conduits entering a building from outside will create corrosion issues for many metallic wiring methods entering a building from outside. Whereas most underground systems are nonmetallic wiring methods, or galvanized rigid, many times EMT is used to run conductors from inside a building to equipment outside the building. We have seen local instances where branch circuit conduit systems were sealed, trapping moisture that then corroded the conduit from the inside out. Requiring these conductors to be sealed can also conflict with the requirement that they be "arranged to drain" as required in 225.22.

Multiple example of this have been observed by local contractors in the Las Vegas area. One such installation problem discovered by a local contractor, Roberts Electric, is described below:

"During the summer of 2013, approximately June or July, our company received an emergency call regarding loss of power to three (3) roof mounted evaporative coolers. All three (3) of the existing coolers were fed from the same branch circuit with separate switching to each cooler.

The pictures illustrate the conduit that left the internal ceiling mounted junction box and traveled approximately ten (10') feet across the warehouse ceiling to the point where it proceeded to pierce the roof membrane and terminate in the combination motor starter located on the roof. The conduit in the pictures had a ninety degree bend where it traveled up through the roof and an additional ninety degree bend where it terminated in the aforementioned electrical junction box. The conduit had been sealed at the electrical junction box and on the roof where it entered the combination motor starter.

Because of the EMT and the temperature difference between the roof conduit and the warehouse conduit, condensation had formed in the conduit. This condensation with nowhere to evaporate began corroding the interior of the conduit and the conductors were sitting in moisture. Eventually this caused the conductor insulation to degrade and this resulted in a fault.

Our company has had several calls for this same commercial property with the exact same scenario. The only difference seems to be the degree of the fault and the damage sustained to the conduit and the conductors."

The photographs referenced above and further details are available if desired.

Organization: SOUTHWEST ELECTRITECH SVCS LLC
Street Address:
City:
State:
Zip:
Submittal Date: Wed Sep 23 21:24:51 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: It is intended to have all raceways that enter a building or structure to be sealed. The requirement to seal raceways where they enter buildings that have temperatures inside that are different from outside (conditioned and unconditioned spaces) is already located in Section 300.7. This requirement simply supports that requirement.
225.27 Raceway Seal.
Where a raceway enters a building or structure from outside an underground distribution system, it shall be sealed in accordance with 300.5(G). Spare or unused raceways shall also be sealed. Sealants shall be identified for use with cable insulation, conductor insulation, bare conductor, shield, or other components.

Statement of Problem and Substantiation for Public Comment

No substantiation was made to make this change which fundamentally revises the requirement in 225.27. In addition, no parallel change was made to 230.8 which puts the two requirements for the same situation out of correlation between Article 225 Outside Branch Circuits and Feeders and Article 230 Services. The purpose of sealing the raceway is discussed in 300.5(G) and in the Informational Note of that same section. Not all raceways entering the building from outside would need to be sealed.

Submittal Date: Mon Jul 27 15:31:33 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: It is intended to have all raceways that enter a building or structure to be sealed. The requirement to seal raceways where they enter buildings that have temperatures inside that are different from outside (conditioned and unconditioned spaces) is already located in Section 300.7. This requirement simply supports that requirement.
225.30 Number of Supplies.
A building or other structure that is served by a branch circuit or feeder on the load side of a service disconnecting means shall be supplied by only one feeder or branch circuit unless permitted in 225.30(A) through (F). For the purpose of this section, a multiwire branch circuit shall be considered a single circuit.

Where a branch circuit or feeder originates in these additional buildings or other structures, only one feeder or branch circuit shall be permitted to supply power back to the original building or structure, unless permitted in 225.30(A) through (F).

(A) Special Conditions.
Additional feeders or branch circuits shall be permitted to supply the following:

1. Fire pumps
2. Emergency systems
3. Legally required standby systems
4. Optional standby systems
5. Parallel power production systems
6. Systems designed for connection to multiple sources of supply for the purpose of enhanced reliability
7. Electric vehicle charging systems listed, labeled, and identified for more than a single branch circuit/feeder

(B) Special Occupancies.
By special permission, additional feeders or branch circuits shall be permitted for either of the following:

1. Multiple-occupancy buildings where there is no space available for supply equipment accessible to all occupants
2. A single building or other structure sufficiently large to make two or more supplies necessary

(C) Capacity Requirements.
Additional feeders or branch circuits shall be permitted where the capacity requirements are in excess of 2000 amperes at a supply voltage of 1000 volts or less.

(D) Different Characteristics.
Additional feeders or branch circuits shall be permitted for different voltages, frequencies, or phases, or for different uses such as control of outside lighting from multiple locations.

(E) Documented Switching Procedures.
Additional feeders or branch circuits shall be permitted to supply installations under single management where documented safe switching procedures are established and maintained for disconnection.

(F) One- or Two-Family Dwelling Unit(s).
For a one- or two-family dwelling unit(s) with multiple feeders, it shall be permissible to install not more than six disconnects grouped at one location where the feeders enter the building, provided the feeder conductors are sized 1/0 or larger and originate at the same location.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs that this First Revision be rewritten to comply with the NEC Style Manual and to clarify the phrase “for more than a single branch circuit/feeder.” Slash markings are not permitted by the NEC Style Manual. In addition, the panel is directed to clarify the phrase “and originate at the same location” in new (F) with the specifics of the feeder origin.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-902-NFPA 70-2015
Statement: Part (A)(7) was revised to comply with the Style Manual.

Part (F) was revised to clarify where the feeder connectors are intended to originate.
Section 225.30(F)

One- or Two-Family Dwelling Unit(s).

For a one- or two-family dwelling unit(s) with multiple feeders, it shall be permissible to install not more than six disconnects grouped at one location where the feeders enter the building, provided the feeder conductors are sized 1/0 or larger and originate at the same location.

Statement of Problem and Substantiation for Public Comment

This is an excellent change! We have for years wrestled with the code where the power company would only provide service from a meter pedestal with one or two 200 A breakers. If the structure requirements exceeded 200 A for a single feeder, we were forced to rely on the logic found in 230.2(C)(2), understanding we had feeder, not service conductors. This solves that problem! Good work!

Submittal Date: Wed Jun 24 15:08:59 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The submitter has not presented any recommended changes.
Public Comment No. 793-NFPA 70-2015 [Section No. 225.30(F)]

(F) One- or Two-Family Dwelling Unit(s).

For multiple feeders shall be permitted for one- or two-family dwelling unit(s) with multiple feeders, it shall be permissible to install not more than six disconnects grouped at one location where the feeders enter the building, provided the feeder conductors are sized 1/0 or larger and originate at the same location.

Statement of Problem and Substantiation for Public Comment

IEC’s position is to delete wording and revise wording in 225.30(F) to improve clarity—(FR 921)

The grouping of disconnects is already required in 225.34 and the maximum number is stated in 225.33; adding this to 225.30(F) is redundant. The location of the disconnecting means is covered in 225.32.

IEC respects the safety concern of the panel and recognizes that feeders are very different than service conductors in that feeders have overcurrent protection. Multiple feeders are installed in buildings in accordance with Article 215 and there is no requirement to have a disconnecting means at the termination point of the feeder. The words “where the feeders enter the building” could cause problems for the installer and additional expense for the home owner without enhancing safety. For instance, a service structure could be built 15 feet away from the house and all service equipment is installed on the structure. The main disconnect and the feeder disconnects are in a main distribution panel at the service structure. An AHJ could require additional disconnects at the house even though the required disconnects are readily accessible and grouped in the main distribution panel. Firefighters would be able to disconnect all power by turning off the main disconnect.

IEC does not understand the minimum size of 1/0 or larger for a feeder. What Code provision is being violated with a #3 THWN conductor that is protected at its supply with a 100 amp overcurrent protective device, provided the conditions of use allow the #3 to be used at its 100 amp rating? The minimum size of feeders is addressed in 215.2.

Submittal Date: Sun Sep 20 18:09:11 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The original language that the CMP approved in the First Draft was intended to limit the number of feeders entering a building to no more than six. This number aligns with similar requirements found elsewhere in the NEC relative to power entering buildings. The minimum size of 1/0 was chosen to align with the minimum sizing allowed for parallel conductor installations. Multiple feeders with conductors smaller than 1/0, such as the #3 that the submitter references, could be combined into a single larger feeder.
225.32 Location.

The disconnecting means shall be installed either inside or outside of the building or structure served or where the conductors pass through the building or structure. The disconnecting means shall be at a readily accessible location nearest the point of entrance of the conductors. For the purposes of this section, the requirements in 230.6 shall be utilized.

Exception No. 1: For installations under single management, where documented safe switching procedures are established and maintained for disconnection, and where the installation is monitored by qualified individuals, the disconnecting means shall be permitted to be located elsewhere on the premises.

Exception No. 2: For buildings or other structures qualifying under the provisions of Article 685, the disconnecting means shall be permitted to be located elsewhere on the premises.

Exception No. 3: For towers or poles used as lighting standards, the disconnecting means shall be permitted to be located elsewhere on the premises.

Exception No. 4: For poles or similar structures used only for support of signs installed in accordance with Article 600, the disconnecting means shall be permitted to be located elsewhere on the premises.

Exception No. 5: For electric vehicle charging systems, the disconnecting means shall be installed in accordance with 625.42.

Statement of Problem and Substantiation for Public Comment

Delete the proposed new exception.

The action taken by CMP-1 on FR 13 to revise the defined term "structure" resolves the issue and concern raised by the submitters of PI's 3924 and 4610. The revised definition will be as follows:

Structure. That which is built or constructed, other than equipment.

The addition of the words "other than equipment" addresses the issue raised in the PI's. Additionally the proposed revision would allow unlimited lengths of conductors inside a building or structure. Vehicle charging equipment is not limited to outdoors only and 625.42 only requires the disconnecting means be "readily accessible". There is no requirement in Article 625 that addresses an outside branch circuit or feeder entering a building or structure. Article 625 relies on the general rule in 225.32 for the location of the disconnect.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-903-NFPA 70-2015
Statement: Exception 5 was removed, as this requirement was already addressed elsewhere in the Code.
(C) Disconnection of Grounded Conductor.

Where the building or structure disconnecting means does not disconnect the grounded conductor from the grounded conductors in the building or structure wiring, other means shall be provided for this purpose at the location of the disconnecting means. A terminal or bus to which all grounded conductors can be attached by means of pressure connectors shall be permitted for this purpose.

In a multisection switchboard or switchgear, disconnects for the grounded conductor shall be permitted to be in any section of the switchboard or switchgear, if the switchboard section or switchgear section is marked to indicate a grounded conductor disconnect is located within.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs that Code-Making Panel 4 clarify the use of the phrase “is located within.”

Committee Statement

Committee Action: Rejected but see related SR  
Resolution: SR-904-NFPA 70-2015  
Statement: The text was revised to better indicate where the grounded conductor disconnect is located.
TITLE OF NEW CONTENT

Type your content here ...

225.41 Surge Protection for Outside Feeders. All outside feeders supplying buildings or other structures shall include a listed
Type 1 or Type 2 surge protective device (SPD). The SPD shall be located in the disconnecting means, or immediately adjacent
to the disconnecting means that is required by 225.31.

Exception: Surge protection is not required for non-habitable buildings or other structures supplied from outside feeders that
originate in one- and two-family dwellings.

Statement of Problem and Substantiation for Public Comment

The Committee Statement to resolve PI 2796 suggests that surge protection should be optional, at the discretion of the property owner.
Surge protection is very similar to overcurrent protection in that it is needed to minimize equipment damage due to voltage surges.
Since it is unreasonable to claim that surge voltages are not causing property damage, CMP 4 is encouraged to treat overvoltage
protection in a manner similar to overcurrent protection.

Organization: Eaton
Affiliation: Eaton
Street Address: Eaton
City:
State:
Zip:
Submittal Date: Wed Sep 23 16:32:09 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: Surge protection may protect some electrical equipment from unwanted electrical surges that enter the electrical system.
The submitter has not presented any technical substantiation to support mandating this equipment for every feeder that
enters a building. Building occupants that are concerned with potential electrical surges are permitted to install this
equipment in either service equipment or feeder equipment already.
225.41 Electrical Service Areas

At least one 125-volt, single-phase, 15- or 20-ampere-rated receptacle outlet shall be installed in an accessible location within 7.5 m (25 ft) of the outdoor electrical service equipment.

Exception No. 1: The receptacle outlet shall not be required to be installed outside of one- and two-family dwellings.

Exception No. 2: Where the service voltage is greater than 120 volts to ground, a receptacle outlet shall not be required for services dedicated to equipment covered in Articles 675 and 682.

Statement of Problem and Substantiation for Public Comment

In creating First Revision FR 323 to 210.64 to address cord sets running through open doors of electrical service areas, Code-Making Panel 2 explicitly rejected those portions of PI 1439 and 3344 that advocated for removal of these requirements for outdoor electrical service areas other than irrigation machines of Article 675 and artificial bodies of water of Article 682 due to remoteness. CMP-2 Statement for First Revision 323 reads:

"PI 1439 and 3344: The panel did NOT AGREE that the receptacle required should ONLY BE REQUIRED FOR INDOOR SERVICES. A requirement that the receptacle be included in the service ROOM did not address similar needs for OUTSIDE SERVICES."

These requirements prior to FR 323 nonetheless encompass both indoor and outdoor electrical service areas. Outdoor electrical service areas however are addressed by Article 225 under the responsibility of CMP-4, not CMP-2. Accordingly, for correlation, the existing requirements for outdoor electrical service areas, except for the revisions for 25 ft distance and the exemptions for irrigation machines and artificial bodies of water, should be now maintained in Article 225.

Committee Statement

Committee Action: Rejected

Resolution: Article 225 addresses outside feeder installations not service equipment. Requirements for the placement of receptacle outlets is under the purview of CMP 2 and should be addressed there.
Public Comment No. 40-NFPA 70-2015 [Section No. 225.61]

225.61 Clearances over Buildings and Other Structures.

(A) 22 kV Nominal to Ground or Less.

The clearances over buildings and other structures for conductors and live parts up to 22 kV, nominal, to ground or less shall be not less than the values shown in Table 225.61.

(B) Over 22 kV Nominal to Ground.

Clearances for the categories shown in Table 225.61 shall be increased by 10 mm (0.4 in.) per kV above 22,000 volts.

Informational Note: For additional information, see ANSI C2-2007, IEEE C2-2012, National Electrical Safety Code.

Committee Statement
Committee Action: Rejected
Resolution: There is no technical rationale to allow supplying electric vehicle charging equipment with more than one service. The requirements located in Section 225.30 and those located in Section 230.2 are similar but are dramatically different based on the source of electricity supplying each.
Public Comment No. 346-NFPA 70-2015 [New Section after 230.3]

230.4 Services Separate on Load-Side of Service Disconnect - PI 1187

Committee Comment – PI 1187, Additional Substantiation

The resolution statement doesn’t address the issue of two utility sources tied together through customer wiring as depicted on the previously submitted PI files. In addition to the initial PI substantiation, the equipment grounding conductors between the two services creates a parallel path with the utility’s grounded system neutral. The utility’s fault or unbalanced current can flow through the customer’s wiring. Obviously, this creates the opportunity for stray voltage/current through customer wiring. This is a safety concern and can create a possible catastrophic event. From a NEC standpoint, this PI will help mitigate possible stray voltage/current caused by customer wiring.

- **City:**
- **State:**
- **Zip:**
- **Submittal Date:** Fri Sep 25 16:20:32 EDT 2015

**Committee Statement**

- **Committee Action:** Rejected
- **Resolution:** This type of connection could actually introduce a hazard as it does not provide a solid ground fault current return path back to the source. Bonding the metal structure to a local grounding electrode would energize this bonding conductor in the event of a conductor fault at the support structure location. With no ground detector system available this conductor and the associated electrode would be energized at the voltage level of the faulted conductor and would become a severe shock hazard and potentially a fire hazard. The structures that are being described in this Section are elevated at the rooftop location and thus even if energized do not pose a substantial shock hazard. When dealing with a grounded system connecting the system grounded conductor to the steel support tower provides a path for fault currents back to the utility transformer.
**Public Comment No. 360-NFPA 70-2015 [Section No. 230.29]**

230.29 - Supports over Buildings.

Service conductors passing over a roof shall be securely supported by substantial structures. For a grounded system, where the substantial structure is metal, it shall be bonded by means of a bonding jumper and listed connector to the grounded overhead service conductor. The bonding jumper shall be of the same conductor size and material as the grounded overhead service conductor. Where practicable, such supports shall be independent of the building.

**Statement of Problem and Substantiation for Public Comment**

I'm not trying to be rude, but this panel does not have the ability to write Grounding and Bonding rules. Either delete or have Panel 5 assist in the language. I don't want to go into the details on the many issues I have but let's just start with bonding jumper sizing?...

### Committee Statement

- **Committee Action:** Rejected
- **Resolution:** The panel accepted the word “approved” in this application as the local AHJ would have the knowledge of soil and environmental conditions and thus the applicability of a particular bare conductor type.
230.41 Insulation of Service-Entrance Conductors.

Service-entrance conductors entering or on the exterior of buildings or other structures shall be insulated.

*Exception: A grounded conductor shall be permitted to be uninsulated as follows:*

1. Bare copper used in a raceway or part of a service cable assembly
2. Bare copper for direct burial where bare copper is approved, is identified for the soil conditions
3. Bare copper for direct burial without regard to soil conditions where part of a cable assembly identified for underground use
4. Aluminum or copper-clad aluminum without individual insulation or covering where part of a cable assembly or identified for underground use in a raceway, or for direct burial
5. Bare conductors used in an auxiliary gutter

Statement of Problem and Substantiation for Public Comment

This section has been proposed to be changed from "judged to be suitable" for the soil conditions to "approved" for the soil conditions. Perhaps a better choice of words here would be "identified" for the soil conditions. Who does approving? According to Article 100, the authority having jurisdiction (AHJ) does approving. The AHJ could "approve" any type of a conductor in this situation. As an AHJ, I greatly depended upon identified products by a third-party testing agency to base my approval. See the definition of "identified" in Article 100.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company's name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-910-NFPA 70-2015
Statement: The word "or" was changed to "and" to clarify that equipment that is listed shall also be labeled to assist AHJs in determining whether the equipment is listed during an inspection.

This section was modified to be expressed in a similar fashion to similar requirements found in other parts of the Code.
(A) General.

The ampacity of service entrance conductors shall have an ampacity of not be smaller than the largest less than the maximum load to be served. Conductors shall be sized to carry not less than the required in 230.42(A)(1), (A)(2), or (A)(3). Loads shall be determined in accordance with Part III, IV, or V of Article 220, as applicable. Ampacity shall be determined from 310.15. The maximum allowable current of busways shall be that value for which the busway has been listed or labeled.

(1) The sum of the. Where the service-entrance conductors carry continuous or any combination of noncontinuous and continuous loads, the minimum service-entrance conductor size shall have an allowable ampacity not less than the sum of the noncontinuous loads plus 125 percent of continuous loads.

Exception: Grounded conductors that are not connected to an overcurrent device shall be permitted to be sized at 100 percent of the continuous and noncontinuous load.

(2) The sum of the minimum service-entrance conductor size shall have an ampacity not less than the sum of the noncontinuous load plus the continuous load after the application of any adjustment or correction factors.

(3) The sum of the noncontinuous load plus the continuous load if the service-entrance conductors terminate in an overcurrent device where both the overcurrent device and its assembly are listed for operation at 100 percent of their rating.

Statement of Problem and Substantiation for Public Comment

Public Input 1270 was an attempt to provide consistency in the applications of 210.19(A)(1), 215.2(A)(1), and 230.42(A) and distinguish when allowable ampacity and ampacity should be used. As currently written, the ampacity of a service-entrance conductor is required to be not less than the noncontinuous load and 125% of the continuous load. Since ampacity is defined in Article 100 as being the maximum current the conductor can safely carry under conditions of use, 230.42(A)(2) is in conflict with 230.42(A)(1). As stated in 230.42(A)(2), is it not redundant to state after the application of adjustment and correction factors since the definition of ampacity already states conditions of use? If it is the panel's intent that 230.42(A)(1) would apply to a conductor's allowable ampacity, without adjustment and correction factors, then the text of the Code should clarify the rule by using the allowable ampacity and not ampacity. As stated in public comments 373 and 393, I would additionally ask the panel if there is a difference between allowable ampacity and ampacity? The allowable ampacity, which does not consider conditions of use, should be compared to the load as stated in 230.42(A)(1), and the ampacity, which considers conditions of use, should be compared to the load as stated in 230.42(A)(2).

Resolution: SR-910-NFPA 70-2015
Statement: The word "or" was changed to "and" to clarify that equipment that is listed shall also be labeled to assist AHJs in determining whether the equipment is listed during an inspection.

This section was modified to be expressed in a similar fashion to similar requirements found in other parts of the Code.
230.44 Cable Trays.
Cable tray systems shall be permitted to support service-entrance conductors. Cable trays used to support service-entrance conductors shall contain only service-entrance conductors and shall be limited to the following methods:

1. Type SE cable
2. Type MC cable
3. Type MI cable
4. Type IGS cable
5. Single conductors 1/0 and larger that are listed for use in cable tray, or cable assemblies with Type TC rating

Such cable trays shall be identified with permanently affixed labels with the wording “Service-Entrance Conductors.” The labels shall be located so as to be visible after installation with a spacing not to exceed 3 m (10 ft) so that the service-entrance conductors are able to be readily traced through the entire length of the cable tray.

Exception: Conductors, other than service-entrance conductors, shall be permitted to be installed in a cable tray with service-entrance conductors, provided a solid fixed barrier of a material compatible with the cable tray is installed to separate the service-entrance conductors from other conductors installed in the cable tray.

Statement of Problem and Substantiation for Public Comment

The language "or Cable Assemblies with Type TC rating" is confusing since "cable assemblies" is not defined and "Type TC" is a cable wiring method that has not been evaluated for use as service conductors in cable tray.

Submittal Date: Mon Sep 28 15:13:25 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-911-NFPA 70-2015
Statement: The section was revised to establish Power Tray Cable as an individual item and to clarify what cable types can be used as service-entrance conductors in cable trays.
Revise FR 933 as follows:

230.44 Cable Trays.

Cable tray systems shall be permitted to support service-entrance conductors. Cable trays used to support service-entrance conductors shall contain only service-entrance conductors, and shall be limited to the following methods:

- Type SE cable
- Type MC cable
- Type MI cable
- Type IGS cable
- Single conductors 1/0 and larger that are listed for use in cable tray or cable assemblies with Type TC rating

Such cable trays shall be identified with permanently affixed labels with the wording “Service-Entrance Conductors.” The labels shall be located so as to be visible after installation with a spacing not to exceed 3 m (10 ft) so that the service-entrance conductors are able to be readily traced through the entire length of the cable tray.

Exception: Conductors, other than service-entrance conductors, shall be permitted to be installed in a cable tray with service-entrance conductors, provided a solid fixed barrier of a material compatible with the cable tray is installed to separate the service-entrance conductors from other conductors installed in the cable tray.

Statement of Problem and Substantiation for Public Comment

By limiting the service conductors permitted in cable trays systems to the five listed items many other methods permitted in 392.10(A) and 230.43 that provide safe physical protection of service conductors are prohibited without any substantiation. Cable tray systems are not a wiring method they are only a support system that may be used to support all types of wiring methods and single conductors under limited conditions. Please accept this change.

Committee Statement

Committee Action: Rejected
Resolution: This Section is intended to define the cable wiring methods that are allowed to be used for service-entrance in cable trays. This does not prohibit the use of other acceptable wiring methods as defined in Section 230.43 from being supported by a cable tray provided the requirements for cable trays are followed.
230.53 Raceways to Drain.
Where exposed to the weather, raceways enclosing service-entrance conductors shall be listed or approved for listed and identified for use in wet locations and arranged to drain. Where embedded in masonry, raceways shall be arranged to drain.

Statement of Problem and Substantiation for Public Comment
This section has been proposed to be changed from "suitable for use" in wet locations to "listed or approved" in wet locations. Perhaps a better choice of words here would be "listed and identified" in wet locations. Who does approving? According to Article 100, the authority having jurisdiction (AHJ) does approving. The way this section has been proposed, the AHJ could accept a listed raceway here (listed for what?), or the AHJ could accept ANY raceway he or she "approved" (and it would not have to be listed). Changing this proposed text to "listed AND identified" in a wet location takes the guess work out of the equation as AHJ could now depend upon identified products by a third-party testing agency to base an approval on. See the definition of "identified" in Article 100.

Submittal Date: Mon Sep 21 14:50:53 EDT 2015

Committee Statement
Committee Action: Rejected
Resolution: This section is intended to allow the use of raceways that are listed for wet locations or to allow the AHJ to approve a raceway for wet locations where they deem appropriate. There may be installation criteria where a particular raceway is not listed for wet locations but the AHJ deems it acceptable in that location. Therefore, that installation would fall under the definition of "approved."
Service heads on raceways equipped with a service head or service-entrance cables, and goosenecks in service-entrance cables shall be located above the point of attachment of the service-drop or overhead service conductors to the building or other structure.

Exception: Where it is impracticable to locate the service head or gooseneck above the point of attachment, the service head or gooseneck location shall be permitted not farther than 600 mm (24 in.) from the point of attachment.

Statement of Problem and Substantiation for Public Comment

The current wording requires that the raceway be installed above the point of the service drop or overhead service conductor point of attachment. It is the service head and not the complete raceway that needs to be above the point of attachment.

Public Comment No. 1265-NFPA 70-2015 [New Section after 230.66]

Title of New Content
Type your content here ...

230.67 Surge Protection.
(A) Surge Protective Device. All services shall be provided with a surge protective device (SPD).
(B) Location. The surge protective device shall be an integral part of the service disconnecting means or shall be located immediately adjacent thereto.
(C) Type. The surge protective device shall be a Type 1 or Type 2 SPD.
(D) Replacement. Where service equipment is upgraded, all of the requirements of this section shall apply.

Statement of Problem and Substantiation for Public Comment
Surge protection is very much like overcurrent protection in that it is necessary to protect at every level within the system. Overcurrent protection is required at the service entrance, at the feeders and at the branch circuits. Proper surge protection is very similar. And, surge protection must be required, just like overcurrent protection is required. Significant losses occur every year because of voltage surges. That fact cannot be denied. Our real problem is that there are insufficient requirements for surge protection, allowing for such large amounts of surge damage. Surge protection is not optional if damage is to be avoided, just like overcurrent protection is not optional if damage is to be avoided.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product a as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

Submittal Date: Fri Sep 25 08:10:40 EDT 2015

**Committee Statement**

Committee Action: Rejected  
Resolution: The language as submitted would only apply to meter socket enclosures. Article 110 already has requirements for the marking of equipment for available fault current.
230.66 Marking.
Service equipment rated at 1000 volts or less shall be marked to identify it as being suitable for use as service equipment. All service equipment shall be listed or field labeled. Individual meter socket enclosures shall not be considered service equipment but shall be listed and rated for the voltage and ampacity of the service.

Exception: Meter sockets purchased or purchased and under the exclusive control of an electric utility are not required to be listed.

Statement of Problem and Substantiation for Public Comment

The original intent of the exception was to exempt only utility purchased meter sockets from being listed and labeled. The word "or" would exempt all meter sockets regardless of who purchased them once the meter is installed and the utility seal is applied, thus making the meter socket under the exclusive control of the utility. Therefore, the word "or" should be changed to "and".

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-913-NFPA 70-2015
Statement: The Exception was revised to clarify that meter socket enclosures that are both purchased and under the exclusive control of a utility company do not have to be listed.

Listed equipment is also required to be labeled to assist AHJs in determining whether the equipment is listed during an inspection.
230.66 Marking.

Service equipment rated at 1000 volts or less shall be marked to identify it as being suitable for use as service equipment. All service equipment shall be listed or field labeled. Individual meter socket enclosures shall not be considered service equipment but shall be listed and rated for the voltage and ampacity of the service.

Exception: Meter sockets purchased or under the exclusive control of an electric utility are not required to be listed.

Statement of Problem and Substantiation for Public Comment

IEC's position is to delete the exception for 230.66

The exception to allow meter sockets to be unlisted is unclear. By the literal reading of the text anytime a meter socket is purchased, whether the socket is under the exclusive control of the utility or not, it would not be required to be listed. We don’t think that was the intent. If a person were to go to the supply house to buy a meter socket that is approved by the local utility is the meter required to be listed? Or does this mean the meter sockets purchased from a utility are not required to be listed? All meter sockets need to be rated for load and short circuit current and allowing non-listed products appears to reduce safety. There will always be controversy over whether meter sockets are covered by the NEC as stated in 90.2(3) or if they fall under 90.2(B)(5)a. The meter socket should be covered by the NEC and the meter or metering equipment should not be covered.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-913-NFPA 70-2015
Statement: The Exception was revised to clarify that meter socket enclosures that are both purchased and under the exclusive control of a utility company do not have to be listed.

Listed equipment is also required to be labeled to assist AHJs in determining whether the equipment is listed during an inspection.
(A) Dwellings
Where installed on one-family and two-family dwellings, the service disconnecting means shall be installed outside the structure at the nearest point of entrance of the service conductors.

Statement of Problem and Substantiation for Public Comment

This public comment is submitted on behalf of the IAFF in response to the resolution of PI 4224, wherein the Panel Statement reads: "This requirement is overly onerous and not necessary. Why is the hazard greater in a one or two family dwelling than it is in a multi-family dwelling or commercial building? Larger services for these types of buildings actually pose more of a hazard."
The PI was written to address the challenges on one-family and two-family dwellings. It does not take a position of comparable hazards levels of multi-family or high-rise occupancies. The key to this public comment request, is the lack of an external service disconnect for safe fire fighter operations within a residential structure. From the mid 1970’s forward, it has been acknowledged that using a meter as a service disconnect is a dangerous practice for fire fighters to secure utilities, yet the code has not been modified to provide a safer NFPA70E-compliant alternative. Many emergencies may make the need to cut electrical power such as fires, gas leaks, structural damage, & flooding. To require that personnel enter a potentially hazardous environment to perform this task, when a well-established method is available, is the basis of this reasonable safety code modification.
The comments on environmental effects on enclosures is a UL standards compliance issue, and should be addressed under use of the appropriate listed enclosure. This is not an overly onerous requirement as proven by the many utilities in many states that require an external method to disconnect power in an emergency without requiring responders to enter the structure to secure power.

Submittal Date: Tue Sep 22 17:41:23 EDT 2015

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-1004-NFPA 70-2015
Statement: By providing an external disconnect, this allows for the safe interruption of utility power from outside the structure. The requirement for a remote controlled device allows for exterior activation of an interior device as per 230.70(A)(3).

The effective date will allow time for implementation into new products.
(1) **Readily Accessible Location.**

The service disconnecting means shall be installed at a readily accessible location either outside of a building or structure or inside nearest the point of entrance of the service conductors.

**Exception:** A service disconnecting means for residential occupancies shall be installed outside the structure nearest the point of entrance of the service entrance conductors.

**Statement of Problem and Substantiation for Public Comment**

Fire fighters should not be required to pull a meter in order to disconnect a residential service, unless of course, the meter and meter socket are tested and listed as a disconnecting means. In addition the the increased safety for firefighters trying to disconnect the service, acceptance of this Public Comment would provide an additional degree of safety by allowing for the incoming lugs of an indoor residential panelboard to be de-energized while work is being performed in the panelboard. Finally, if the service disconnecting means also includes the service overcurrent protective device, additional protection is provided for the service entrance conductors, conductors that are not now protected from short-circuits between the meter and the service entrance overcurrent protective device.

Public Comment No. 1591-NFPA 70-2015 [Section No. 230.70(A)(1)]

(1) _Readily Accessible Location._

The service disconnecting means shall be installed at a readily accessible location either outside of a building or structure or inside nearest the point of entrance of the service conductors. In new buildings, excluding one- and two-family dwellings, a disconnect to the building shall be provided as follows:

(a) In the Fire Command Center, where a Fire Command Center is provided in the building.
(b) At the fire alarm annunciator, where there is no Fire Command Center.
(c) In an appropriately sized and weatherproofed fire department access box on the address side of the building, where there is no fire alarm annunciator or Fire Command Center.

In existing buildings, excluding one- and two-family dwellings, where there are significant upgrades to the building electrical service, such as modifying or replacing the switchgear, a disconnecting means shall be provided as for new buildings.

Statement of Problem and Substantiation for Public Comment

This is a firefighter safety issue. It is intended to allow a firefighter to disconnect the power to a building without the need to go searching for the disconnect in an involved building. Down to the third floor or a parking garage below the building to kill the electricity to the entire building.

It is correct in assuming it will not de-energize ALL circuits. However whether you wait for the firefighter to locate the disconnecting means (losing valuable time) or if you shunt trip the main the result will be the same. The emergency circuits will still be energized. Throughout the NEC greater protection for emergency circuits and especially emergency feeders is required thus reducing the accidental physical damage by firefighter and or fire. By de-energizing the main you will reduce the number of energized circuits by 75% or greater. This will provide greater protection for our first responders. By shunt tripping the main at the fire command center it will save time and possibly reduce the threat of injury or death to our first responders. There are jurisdictions that will not allow firefighters into a building until the utility company arrives and de-energizes the building due to risking their responders lives while searching through the building for the disconnect.

It does require control wires but a shunt trip module (coil unit) must be factory installed on a new installation or field installable on existing breakers for substantial renovations. The cost varies. But in talking with various manufacturers, most of their main breakers (originating back to the 1950's) can be field installed with shunt trip devices at a cost of $1000 or less for the module. If the main disconnecting means uses fused disconnects, it might be more to meet the requirement on a remodel if this is the case.

This can be easily achieved at a cost much less than what we are currently requiring for rapid shutdown of photovoltaic systems. That requirement was adopted to protect our first responders, and so should this.

If the CMP wants to consider not applying this to existing buildings, then the last paragraph could be deleted. Consideration could also be made to applying this only to new buildings with Fire Command Centers.

Street Address: 
City: 
State: 
Zip: 
Submittal Date: Fri Sep 25 14:57:06 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: This requirement if accepted is excessive and with no technical substantiation other than it would potentially enhance firefighter safety. The ease of compliance as described by the submitter is simplistic, and it would not be easy in all instances. As proposed the requirement would apply to all buildings other than one or two family dwellings. There are...
many buildings in this category that wouldn’t have any of the described locations for the initiation device to be located. Firefighter safety is of utmost importance, however, there is no technical information provided with the submittal to validate that it would in fact enhance safety. A requirement of this magnitude should be available for review by the general public and inserting it at the second revision stage would not allow for that type of review. The submitter may want to consider resubmitting the proposed change during the next cycle with more technical documentation.
(1) **Readily Accessible Location.**

The service disconnecting means shall be installed at a readily accessible location either outside of a building or structure or inside nearest the point of entrance of the service conductors.

**(A) Dwellings**

Where installed on one family and two family dwellings, the service disconnecting means shall be installed outside the structure at the nearest point of entrance of the service conductors or provide a shunt trip breaker with actuation located on the outside of the structure near the service entrance.

**Statement of Problem and Substantiation for Public Comment**

This requirement would further enhance the safety of the emergency responders. Many emergencies may require disconnection of electrical power such as fires, gas leaks, structural damage, & flooding. Requiring that personnel enter a potentially hazardous environment to perform this task, when a well established method is available that would comply with the requirements of NFPA 70 E, is the basis of this reasonable safety code modification.

Resolution: SR-1004-NFPA 70-2015
Statement: By providing an external disconnect, this allows for the safe interruption of utility power from outside the structure. The requirement for a remote controlled device allows for exterior activation of an interior device as per 230.70(A)(3). The effective date will allow time for implementation into new products.
Public Comment No. 1764-NFPA 70-2015 [Section No. 230.71(A)]

(A) General.

The service disconnecting means for each service permitted by 230.2, or for each set of service-entrance conductors permitted by 230.40, Exception No. 1, 3, 4, or 5, shall consist of not more than six switches or sets of circuit breakers, or a combination of not more than six switches and sets of circuit breakers, mounted in a single enclosure, in a group of separate enclosures, or in or on a switchboard or in switchgear. There shall be not more than six sets of disconnects per service grouped in any one location.

For the purpose of this section, disconnecting means installed as part of listed equipment and used solely for the following shall not be considered a service disconnecting means:

(1) Power monitoring equipment
(2) Surge-protective device(s) that are installed in accordance with 285.23
(3) Control circuit of the ground-fault protection system
(4) Power-operable service disconnecting means

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs that Code-Making Panel 4 reconsider the added requirement to be installed in accordance with 285.3 since 90.3 already requires compliance with 285.23

Submittal Date: Mon Sep 28 15:15:16 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-914-NFPA 70-2015
Statement: The deleted text is unnecessary as it is already found in other parts of the NEC.
(C) **Performance Testing.**

The ground-fault protection system shall be performance tested when first installed on site. This testing shall be conducted by a qualified person(s) using a test process of primary or secondary current injection, in accordance with instructions that shall be provided with the equipment. A written record of this testing shall be made and shall be available to the authority having jurisdiction.

**Informational Note No. 1:** Ground-fault protection that functions to open the service disconnect affords no protection from faults on the line side of the protective element. It serves only to limit damage to conductors and equipment on the load side in the event of an arcing ground fault on the load side of the protective element.

**Informational Note No. 2:** This added protective equipment at the service equipment may make it necessary to review the overall wiring system for proper selective overcurrent protection coordination. Additional installations of ground-fault protective equipment may be needed on feeders and branch circuits where maximum continuity of electric service is necessary.

**Informational Note No. 3:** Where ground-fault protection is provided for the service disconnect and interconnection is made with another supply system by a transfer device, means or devices may be needed to ensure proper ground-fault sensing by the ground-fault protection equipment.

**Informational Note No. 4:** See 517.17(A) for information on where an additional step of ground-fault protection is required for hospitals and other buildings with critical areas or life support equipment.

---

**Statement of Problem and Substantiation for Public Comment**

The following is from an article written by Howard Herndon and was published in the Nov/Dec 2010 edition of the IAEI magazine.

"Use of a secondary injection test set will test the electronics of the relay or trip unit, but does not insure the CT installation and wiring are correct. Use of the test-trip button will test the circuit within the relay or trip unit, but again does not insure the CT installation and wiring are correct. This does not meet the intent of performance testing as outlined in NEC 230.95(C). Use of the secondary test set or push-to-test button is like performance testing the safety features of a car while it is up on blocks — it may look good, but is not very effective."

Statement: This revision updates references to current editions in several places.
Tap Conductor.

As used in this article, a tap conductor is defined as a conductor, other than a service conductor, that has overcurrent protection ahead of its point of supply that exceeds the value permitted for similar conductors that are protected as described elsewhere in 240.4.

Statement of Problem and Substantiation for Public Comment

The panel statement indicates that this change is merely editorial, but it has technical implications as well. Even though the definition is located in Article 240, unless the language limits its application to that article, the definition will apply to the term where used in other locations in the Code (just like the definitions of wiring methods found in Articles 320, 330, etc.). The term "tap conductor" is used in many places in the NEC, and the definition proposed will be in conflict with some of those uses. How will the grounding electrode tap conductors referred to in 250.30(A)(6) fit with the newly worded definition for tap conductors? What about the conductors that come out of a tap as allowed in 230.33 for services, how do they fit with this definition that specifically excludes service conductors but now applies generally to other Articles in the NEC? Will this create a conflict between 430.28 and 240.21? There are numerous other references to "tap conductor" in the NEC, and the definition approved in FR 2702 will create technical changes to the code that have not been substantiated or adequately addressed. These issues are far more important to code users than a possible conflict with the style manual.

Submittal Date: Wed Sep 23 21:51:40 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: Definitions located in the XXX.2 section of an Article apply only to that Article. See the scope of Article 100 which indicates definitions in Article 100 apply to multiple articles.
A set of conductors feeding a single load, or each set of conductors feeding separate loads, shall be permitted to be connected to a transformer secondary, without overcurrent protection at the secondary, as specified in 240.21(C)(1) through (C)(6). The provisions of 240.4(B) shall not be permitted for transformer secondary conductors.

Exception: When the transformer primary overcurrent device has a rating or setting that does not exceed 150 percent of the value determined by multiplying the secondary conductor ampacity by the secondary-to-primary transformer voltage ratio, the provisions of 240.4(B) shall be permitted.

Informational Note: For overcurrent protection requirements for transformers, see 450.3.

Statement of Problem and Substantiation for Public Comment

PI 4635 was submitted to address the fact that industrial installations are permitted to use a simple formula to verify that secondary conductors are permitted to be protected by a primary overcurrent device and commercial customers should be afforded the same opportunity. The language in 240.92(C)(2) allows industrial users of the code to protect transformer secondary conductors as long as the transformer primary overcurrent device has a rating or setting that does not exceed 150 percent of the value determined by multiplying the secondary conductor ampacity by the secondary-to-primary transformer voltage ratio. This public comment seeks to copy that same language in the exception to 240.21(C).

At the present time transformers secondary conductors must be sized based upon on the secondary overcurrent devices and they cannot be smaller than the device rating. The method in 240.92(C)(2) is simple and will provide correlation between commercial and industrial users.

Committee Statement

Committee Action: Rejected
Resolution: Adequate substantiation has not been provided to show that the secondary conductors would be adequately protected.
Public Comment No. 1440-NFPA 70-2015 [Section No. 240.21(C)(4)]

(4) Outside Secondary Conductors.

Where the conductors are located outside of a building or structure, except at the point of load termination, and comply with all of the following conditions:

(1) The conductors are protected from physical damage in an approved manner.

(2) The conductors terminate at a single circuit breaker or a single set of fuses that limit the load to the ampacity of the conductors. This single overcurrent device shall be permitted to supply any number of additional overcurrent devices on its load side.

(3) The overcurrent device for the conductors is an integral part of a disconnecting means or shall be located immediately adjacent thereto.

(4) The disconnecting means for the conductors is installed at a readily accessible location complying with one of the following:

(5) Outside of a building or structure

(6) Inside, nearest the point of entrance of the conductors

(7) Where installed in accordance with 230.6, nearest the point of entrance of the conductors

Exception to (3) Where Section 225.32, Exception No. 1 applies, and where the arc-flash hazard to operate the secondary disconnecting means is excessive, the primary transformer disconnecting means shall be allowed in lieu of and a secondary disconnect and the installation shall be permanently marked to indicate the location of the disconnecting means. All other requirements of 225.(C)(4) apply.

Statement of Problem and Substantiation for Public Comment

There is a correlation problem not addressed by the panel in their response to my Public Input on this subject, Public Input 1404. Article 225.32, Exception No. 1, specifically allows “For installations under single management, where documented safe switching procedures are established and maintained for disconnection, and where the installation is monitored by qualified individuals, the disconnecting means shall be permitted to be located elsewhere on the premises” however there is no such correlating language in 240.21(C)(4) so this cannot be applied without AHJ approval. AHJ’s are unwilling to approve such deviations under Article 90.4 because of liability concerns. For a recent project at our campus, we were relocating a close-coupled dry-type transformer outside of the building and replacing it with a less-flammable fluid filled pad-mount transformer in order to “phase in” the replacement project for the existing switchgear (using the space made available after the dry-type transformer was moved). As such, the transformer secondary conductors had to be routed from the outdoor location to the existing switchgear location. While we could install these conductors in conduit, the only way we could comply with the tap rules in 240.21 was to provide secondary protection outside the building (the conductors were just over 100 feet from the new transformer location to the switchgear main breaker). We asked for permission to install fuses outside the building in a custom fabricated enclosure to provide secondary protection but to allow the primary disconnecting device to be used in lieu of installing a secondary disconnect where the calculated arc-flash energy at the secondary disconnect would easily exceed 40 cal/cm². The primary disconnecting means in this case was within sight of the location where the fuses would be installed. While the language in Section 225.32 Exception #1 applied in our case, the AHJ was unwilling to take the associated liability with such a deviation under Section 90.4 as the code language in 240.21(C)(4)(3) required the secondary disconnecting means to be adjacent to the fuses. Providing such correlation with the proposed exception allows a safer installation and is in line with other language already in place in the code.

<td>Resolution:</td>
<td>An &quot;excessive&quot; arc-flash hazard is vague and unenforceable. Section 450.14 already requires a disconnecting means on the primary side of the transformer. That disconnecting means can be utilized when the incident energy on the secondary is at a dangerous level. The Panel recognizes this as a correlation issue with Section 225.32 Exception No.1. This requirement is for outside secondary conductors that are not protected at their rated ampacity, while the general requirements in 225.32 address outside feeders that are protected at their rated ampacity.</td>

4. For overcurrent devices adjacent to utilization equipment that they supply, access shall be permitted to be by portable means.

Exception: The use of a tool shall be permitted to access overcurrent devices located within listed industrial control panels or similar enclosures.

Statement of Problem and Substantiation for Public Comment

Delete the exception. Although it appears the exception is meant to solve a problem created by the revision of the defined term "accessible, readily" it creates more problems. What is similar to an industrial control panel, a panelboard, door to an equipment room? A better solution is to return the definition of accessible, readily to that in the 2011 NEC and add a rule to require disconcerting means be readily accessible without the use of a tool.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-2701-NFPA 70-2015
Statement: The word “devices” is removed to improve the readability of the requirement, without changing the intent.
Public Comment No. 14-NFPA 70-2015 [ Section No. 240.60(C) ]

(C) Marking.
Fuses shall be plainly marked, either by printing on the fuse barrel or by a label attached to the barrel showing the following:

1. Ampere rating
2. Voltage rating
3. Interrupting rating where other than 10,000 amperes
4. Current limiting where applicable
5. The name or trademark of the manufacturer

The interrupting rating shall not be required to be marked on fuses used for supplementary protection.

The fuse marking or label shall not be blocked from view or covered by trim.

Statement of Problem and Substantiation for Public Comment

The fuse label is vital in determining both code compliance and trip characteristics. For purposes of determining arc flash incident energy levels, the exact fuse manufacturer and model must be determined, and the engineer or inspector should not be burdened or subjected to unsafe tasks such as removing trim cover on energized systems. Rejecting this proposed code change on the basis of not having enough room or added cost should be classified as criminal neglect should a person be harmed.

Committee Statement

Committee Action: Rejected
Resolution: The submitter has not substantiated a problem with existing code requirements. It is not practical to require that these and other markings be provided in an unobstructed location that can be easily and safely read by an individual making a survey of energized equipment. Individuals performing an incident energy analysis on an existing system must follow all applicable OSHA regulations and the industry standard for electrical safety in the workplace, NFPA 70E.
240.67  Arc Energy Reduction.
Where the ampere rating of the fusible switch is 1200 A or higher, 240.67(A) and (B) shall apply. This requirement shall become effective January 1, 2020.

(A)  Documentation.
Documentation shall be available to those authorized to design, install, operate, or inspect the installation as to the location of the fusible switch(es).

(B)  Method to Reduce Clearing Time.
One of the following shall be provided:

1. Differential relaying
2. Energy-reducing maintenance switching with local status indicator
3. Energy-reducing active arc flash mitigation system
4. A fuse that would open the circuit in 0.07 seconds or less, at or below the available arcing current
5. An approved equivalent means

Informational Note No. 1: An energy-reducing maintenance switch allows a worker to set a disconnect switch to reduce the clearing time while the worker is working within an arc-flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace, and then to set the disconnect switch back to a normal setting after the potentially hazardous work is complete. Informational Note No. 2: An energy-reducing active arc flash mitigation system helps in reducing arcing duration in the electrical distribution system. No change in the disconnect switch or the settings of other devices is required during maintenance when a worker is working within an arc flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace.

Informational Note No. 3: IEEE 1584, IEEE Guide for performing Arc Flash Hazard Calculations, is one of the available methods that provide guidance in determining arcing current.

Statement of Problem and Substantiation for Public Comment

I have suggested under separate public comment that this proposal should be rejected. If the code panel does not agree and chooses to adopt this proposal, then the maintenance mode option in this proposal needs to be reconsidered.

If a maintenance mode feature is provided on a switch, an electrician will have two choices when he works. The switch can be turned off (and lock-out tag-out can be applied) or the electrician can activate the maintenance mode. If he chooses to turn the switch off, safety practices dictate that the electrician must assume that the downstream conductors are still energized until proven otherwise. After all, the conductors may be energized from a different source. If the choice is to activate the maintenance mode rather than turn the switch off, it stands to reason that the electrician must equally assume the conductors may be energized from a different source.

If the electrician turns the switch off, a meter can be used to verify the conductors are not energized. If the maintenance mode is used, there is no way to verify activation, other than to create an arc fault and see what happens.

A maintenance mode is a very bad choice. It offers a false sense of security. Turning the switch off is a far superior method. The option of a maintenance mode should be deleted.

Public Comment No. 1635-NFPA 70-2015 [ Section No. 240.67 ]

240.67  .  Arc Energy Reduction.

Where the ampere rating of the fusible switch is 1200 A or higher, 240.67(A) and (B) shall apply. This requirement shall become effective January 1, 2020.

(A)  .  Documentation.

Documentation shall be available to those authorized to design, install, operate, or inspect the installation as to the location of the fusible switch(es).

(B)  .  Method to Reduce Clearing Time.

One of the following shall be provided:

(1)  .  Differential relaying

(2)  .  Energy-reducing maintenance switching with local status indicator

(3)  .  Energy-reducing active arc flash mitigation system

(4)  .  A fuse that would open the circuit in 0.07 seconds or less, at or below the available arcing current

(5)  .  An approved equivalent means

Informational Note No. 1: An energy-reducing maintenance switch allows a worker to set a disconnect switch to reduce the clearing time while the worker is working within an arc-flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace, and then to set the disconnect switch back to a normal setting after the potentially hazardous work is complete.

Informational Note No. 2: An energy-reducing active arc flash mitigation system helps in reducing arcing duration in the electrical distribution system. No change in the disconnect switch or the settings of other devices is required during maintenance when a worker is working within an arc flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace.

Informational Note No. 3: IEEE 1584, IEEE Guide for performing Arc Flash Hazard Calculations, is one of the available methods that provide guidance in determining arcing current.

Statement of Problem and Substantiation for Public Comment

The substantiation for the proposal is that the benefits of arc energy reduction requirements for circuit breakers in NEC 240.87 have been well established and thus should be added to the requirements for fusible switches. Boltswitch agrees that reducing arc flash energy is a wonderful goal. Never-the-less, it is important that the proposal is appropriate for switches; that it is appropriately placed in the NEC; that it does not conflict with other sections of the NEC, and that it does in fact promote safety. If it does not conform to all four of these criteria, then adoption of this proposal will do a disservice.

It is important to understand that this proposal is reactionary. If adopted, it will not prevent a single arc flash event because it only addresses energy release after an arc flash event happens. Lockout/tagout is proactive. Lockout/tagout prevents arc flash events from happening. If this proposal in any way encourages working on live equipment in lieu of lockout/tagout, this proposal will increase the frequency of arc flash events.

The following points are what need to be considered:

1.) Most switches are manually operated
2.) Many switches were never intended to be anything but manually operated
3.) Definitions mean everything
4.) Unlike switches, CB’s must be able to interrupt overcurrent
5.) Switches are much more affected by this proposal than CB’s were by NEC 240.87
6.) Bad practice to mix two products in the same proposal
7.) Switches are described elsewhere in the NEC
8.) Under-sizing fuses is a good practice
9.) Substantiation is not sound that similar requirements for CB’s is well established
10.) Switch manufacturers are addressing arc reduction by other methods
11.) Switches are designed around lockout/tagout
12.) Switches can be padlocked in the closed position
13.) Switches can have key interlocks
14.) The requirements of this proposal directly conflict with NEC 404.13(A)
15.) The term “fusible switch” is not defined, and is hard to define
16.) Switches have safety features that CB’s do not
17.) This proposal encourages working on energized equipment
18.) This proposal impacts products that do not have a risk problem
19.) This proposal could significantly add to the number of arc flash events
20.) Fuses are replaceable products
Point by Point Analysis:

Point No. 1. Most switches are manually operated

Boltswitch is a leading manufacturer of fusible switches rated 1200 amp and larger. Over the past ten years, three out of every four fusible switches rated 1200 amp and above that Boltswitch manufactured and sold were manually operated. Manually operated switches are important components in safe, electrical systems. This proposal could eliminate all manually operated fusible switches rated 1200 amp and above if fuses are unable to meet the fuse requirements (option 4) of this proposal.

Point No. 2. Many switches were never intended to be anything but manually operated

Fusible manual transfer switches, double throw switches and bypass isolation switches rated 1200 amp and above are standard products for specific applications such as optional standby systems. These switches were never intended to have anything other than a manual operating means. If fuse manufacturers are unable to develop fuses that open under arc fault conditions set forth in this proposal, these manually operated switch products will require a means to open automatically, which literally defy the name and/or definition of the product. I have been around automatic transfer switches that do not function with dependability. They require routine testing and maintenance. Simple, manually-operated switches are extremely dependable, which is exactly what people want and need in a power outage.

Point No. 3. The term “Fusible Switch” is not defined in the NEC

Since I began to participate in the IAEI some 3 to 4 decades ago, it has been drilled into me that definitions mean everything. There are five definitions used in the NEC and NFPA 70E that apply to switches rated 1200 amp and above. Each of the definitions would apply to fusible or non-fusible switches. The definitions are as follows:

1.) “Switching Device” is defined in the NEC and NFPA70E as “A device designed to close, open, or both, one or more electric circuits”.
2.) “Switch, Bypass Isolation” is defined in the NEC as “A manually operated device used in conjunction with a transfer switch to provide a means of directly connecting load conductors to a power source and of disconnecting the transfer switch”.
3.) “Switch, General-Use” is defined in the NEC as “A switch intended for use in general distribution and branch circuits. It is rated in amperes, and it is capable of interrupting its rated current at its rated voltage”.
4.) “Switch, Isolating” is defined in the NEC as “A switch intended for isolating an electrical circuit from the source of power. It has no interrupting rating, and it is intended to be operated only after the circuit has been opened by some other means”.
5.) “Switch, Transfer” is defined in the NEC as “An automatic or non-automatic device for transferring one or more load conductor connections from one power source to another”.

By any of the definitions, a switch (fusible or non-fusible) is not an overcurrent protection device and it is not required to open a circuit automatically.

Four of the five definitions do not require the switch to be capable of opening under load. Only a “Switch, General-Use” is required to be capable of opening the circuit under load. But even with a General-Use Switch, the load current does not need to be greater than the rating of the switch. If this proposal is adopted, it should state specifically the types of switches rated 1200 amp and above that it applies to. The term “switch” is too vague. Per the definitions, a “Switch, General-Use” is the only type of switch that comes close to meeting the requirements.

Point No. 4. Unlike switches, CB’s must be able to interrupt overcurrent

A “Circuit Breaker” is defined in the NEC and in NFPA70E as “A device designed to open and close a circuit by non-automatic means and to open the circuit automatically on a predetermined overcurrent without damage to itself when properly applied within its rating”. This definition did not change due to the adoption of 240.87 in the NEC. Accordingly, unlike switches, circuit breakers have always been required to provide overcurrent protection and have always been required to open circuits automatically. Substantiation that switches should have the same requirements as circuit breakers is not sound.

Point No. 5. Switches are much more affected by this proposal than CB’s were by NEC 240.87

The requirements for arc reduction on circuit breakers had very little impact on the application of circuit breakers. After all, circuit breakers were already overcurrent devices and were already required to open automatically. The impact of this proposal on fusible switches is quite different, assuming fuses cannot meet the requirements of option (4) in most applications. Not only are 75% of the switches sold today manually operated, fusible switches can be hook stick operated or have a simple insulated handle on the crossbar. There is a purpose for these products, and they are used in safe schemes.

Point No. 6. Bad practice to mix two products in the same proposal

This proposal mixes requirements for “switches” and requirements for “fuses” as either/or methods for compliance. “Switches” and “fuses” are separate products, each designed around separate standards, and each with separate NRTL Listing marks. Since two products are involved, the first sentence in the proposal should use the term “fused” instead of “fusible”.

There is a big difference between a “fused” switch and a “fusible” switch. A fusible switch can have dummy fuses installed. Boltswitch sells dummy fuses rated 1200 amp and above on a regular basis specifically for the purpose of mounting in a fusible switch. If this term in this proposal is not changed from “fusible” to “fused”, then this proposal absolutely does not belong in “Article 240, Overcurrent
Protection since by any definition of a switch, a fusible switch with dummy fuses is not an overcurrent protective device. As a manufacturer of fusible switches, I have no control or knowledge regarding which brand of fuses or what size fuses (ampere rating) will be installed in the product, let alone whether the fuses selected will comply with the fuse method offered in the proposal. If the fuses selected can meet the proposal requirement, the fusible switch is not affected, even if the switch is manually operated. If the fuses selected do not meet the requirement, then the burden of compliance apparently shifts to the fusible switch, and the switch will need to be equipped with a means to detect an arc fault event, a means to open automatically, and be capable of interrupting a fault current. If this proposal is adopted and an installation does not comply, which product gets the red tag, the switch or the fuses? This illustrates why mixing two products in the same NEC requirement is a bad idea. If the switch is deemed in violation, which party will be held responsible to provide one of the arc energy reduction methods for compliance? Is it the responsibility of the switch manufacturer? Is it the responsibility of the switchboard manufacturer? Is it the responsibility of the installer? The installer is probably the only party that can install a remedy. This is because a truly functional arc reduction system may require sensors that extend downstream throughout the electrical system.

Point No. 7, Switches are described elsewhere in the NEC

Switches are presently addressed in Article 404 of the NEC. If adopted, some requirements for switches would be in Article 404 and some requirements would be in Article 240. NEC 404.1 provides the scope for switches in the NEC. It is very clear. Only switches rated above 1000 volt are to be covered elsewhere in the NEC. Does this mean this proposal only applies to fusible switches rated above 1000 volts?

Point No. 8, Under-sizing fuses is a good practice

The ability to use smaller rated fuses than the fusible switch rating is an important issue concerning this proposal. Suppose a 2000 amp switch has 1600 amp fuses installed, and the 1600 amp fuses comply with the arc reduction requirements, but 2000 amp fuses would not comply. Would the installation comply with the requirements of this proposal? The practice of under-sizing fuses is not only common, but it should be encouraged more often. It is an outstanding way to reduce arc energy and provide better short circuit protection. Class L fuses are uniquely designed around under-sizing. For example, a 4000 amp fuseholder can accept an 800 amp fuse without modification, or any size in-between. Class L fuses are also rated for use at 100% continuous. Most switches are de-rated (whether they are investigated for use at 100% or not) due to calculating the loads and adding 25%. Accordingly, most switches can have undersized fuses installed without the worry of a fuse opening under normal use. If a fault occurs, an undersized fuse offers better protection because it will react faster. Determining the best size fuse for a particular installation is one reason Boltswitch does not include fuses with the switches we sell. We have no idea what size fuse will be best for the installation.

Point No. 9, Substantiation is not sound that arc energy reduction for CB’s is well established

The substantiation provided in this proposal is that the benefits of arc energy reduction for circuit breakers have been well established. Is this true? Several years ago, OSHA began posting “Fatalities and Catastrophes” on their website, along with a brief description of each event. For the governmental Fiscal Year ending 10/1/2014 (FY14), there were 105 events classified as electrical. Of these events, 55 were identified as happening outdoors ahead of the service equipment. The remainder of 50 events is presumed to have occurred in NEC related equipment. For FY13, there were 74 electrical events. Of these events, 38 occurred outdoors ahead of the service equipment. The remainder of 36 events is presumed to have occurred in NEC related equipment. Accordingly, the number of serious NEC related events identified by OSHA increased from 36 in FY13 to 50 in FY14. Energy reduction for circuit breakers (Article 240.87) became effective in the 2011 NEC. If the benefits are well established, why did the number of serious electrical accidents rise by about 40%?

Point No. 10, Switch manufacturers are addressing arc reduction by other methods

Switch manufacturers are aware of the call for arc energy reduction and have been developing products to address the concerns. These methods are being used without a change in the NEC. Boltswitch believes a better approach than this proposal is to provide arc energy reduction closer to the anticipated arc flash hazards, similar to AFCI for circuit breakers. For example, it is unlikely that a very large fusible switch would directly feed a downstream control panel that requires maintenance or troubleshooting while energized. More likely a smaller safety switch or other disconnecting means is located near the downstream control panel. Fuses are available that reduce arc energy (semiconductor fuses), but they are generally available only in ratings of 1200 amp and smaller, not 1200 amp and larger as the proposal targets. Boltswitch offers methods to install fast-acting, semiconductor fuses in standard 400, 600, 800 and 1200 amp Boltswitch-brand fusible switches. They can be installed in new or existing switches that are either manual or shunt trip operated. (See www.boltswitch.com, Bulletin 148, for a description of the products). Not only should the nearest disconnecting means to where the work is to be performed respond the fastest and limit arc energy the best, consider the chaos that would result if a building main or feeder switch in a large facility suddenly opens due to an arc flash event in a small control panel. It may cause the “additional hazard or increased risk” that initially justified the permits to perform energized work. And the cost of a non- orderly shutdown would most likely exceed the cost of a planned outage.

Boltswitch also offers remote closing solenoids as an option to shunt trip operated switches. The remote closing solenoid is an inexpensive way to provide a means to close and open a switch remotely. This was developed for the chemical industry, where the environment may be more likely to cause an arc flash event.

General Electric, another manufacturer of fusible switches, has recently introduced what they call a “New Generation HPC Switch” with “a REAL arc Flash Hazard Mitigation Solution”. They boast minimizing arc flash exposure by offering fully remote operation for close and open with an internal operating motor, and by offering two modes of “switch (mechanical)” instantaneous protection to supplement the protection provided by the fuses.

The point is, switch manufacturers have already been responding to the request for arc energy reduction. Options are available today, and continue to be developed. However, there is such a variety of applications for fusible switches that no single method fits them all. It is also very important for users to understand that any arc reduction method is not to be construed as reasons to avoid the safest
procedure, which is to de-energize and follow lockout/tagout procedures.

Point No. 11, Switches are designed around lockout/tagout, circuit breakers are not

Switches differ from circuit breakers in that virtually every dead-front switch has padlocking provisions (dead-front means it can be operated by an external handle without opening the enclosure). Padlock provisions are a requirement in switch standards. Circuit breakers are not required to have padlock provisions. Thus, switches are truly designed around lockout/tagout procedures. Circuit breakers are not. Since circuit breakers are not required to have padlock provisions, it is understandable that circuit breakers need the requirements 240.87, and switches do not.

Point No. 12, Switches can be padlocked in the closed position

A very important feature on switches is that they can be padlocked in the ON position. Switches are often mounted outside. Most Firefighters prefer to have switches mounted outside. Some jurisdictions require the service disconnect to be located outside. It is not uncommon for switches to be located in alleyways or the backs & sides of buildings, all very accessible to the public. However, only manually operated switches can be padlocked in the ON position. Shunt trip operated switches or any circuit breaker cannot be padlocked in the ON position. This proposal will force many manually operated switches to become shunt trip operated, which means they can no longer be padlocked “ON”.

Point No. 13, Switches can have key interlocks

Switches can be equipped with key interlocks to lock in the OFF position, ON position, or both. Key interlock schemes are used between multiple products to ensure that each product in the system is in a prescribed position before another action can be taken. Key interlocks have auxiliary contacts and solenoid releases, and can be mounted in many ways, including on doors and panels of electrical equipment. Key interlock schemes can be used to prevent access to energized electrical components. The point is that key interlocks are used on switches in a proactive manner to prevent the occurrence of an arc flash event. Often the switches are manually operated and key interlocked in the ON position to prevent opening the switch under load. This proposal will adversely impact these proactive schemes. Shunt trip operated switches and circuit breakers cannot have key interlocks for locking in the ON position.

Point No. 14, The requirements of this proposal directly conflict with NEC 404.13(A)

NEC 404.13(A) states that isolating switches rated over 1200 amp shall not be opened under load. Isolation switches can be (and often are) fusible switches. This proposal would require these same switches to open a fault current automatically if fuses are not available to comply with option (4). Accordingly, the proposal directly conflicts with the requirements of NEC 404.13(A). The proposal must have an exception for isolating switches. I suppose one can argue that isolating switches need to be non-fusable. It would be a very weak argument. It would be saying that the circuit would be safer if it does not have a fuse in it.

Point No. 15, The term “fusible switch” is not defined, and is hard to define

Many “fusible switches” ultimately have copper bars installed in the fuse gap, commonly called dummy fuses. Boltswitch manufactures and sells dummy fuses as standard items. Would a “fusible switch” with dummy fuses installed be subject to the requirements of this proposal? I would think the answer is no, since the assembly would be the same as a non-fusible switch. But technically the switch itself is still a “fusible switch”. This further supports the need to change the term in the proposal from “fusible switch” to “fused switch”. 430.90 in the NEC is titled “Combination Fuseholder and Switch as Controller”. If a fuseholder (with fuses installed) and a non-fusible switch are combined, would the requirements of this proposal need to be enforced? Now there would be three separately listed products involved, and none of them would be a “fusible switch”. Changing the term “fusible switch” to “fused switch” would add clarity to this situation. I would think that most people would consider the combination to be a “fused switch”.

Point No. 16, Switches have safety features that CB’s do not have

Switches differ from circuit breakers in other ways besides padlock and key interlock provisions. Most commonly, switches usually have visible blades. Many switches have clear barriers as a standard feature or are available with clear barriers. Dead-front covers can be equipped with viewing windows to observe the switch blades without opening doors or exposing any live parts. NEC 404.6(C) requires the load terminals of a switch to be de-energized when the switch is in the open position unless marked with a permanent sign on the outside of the enclosure. Accordingly, a properly installed switch with a viewing window can be verified as being OFF without opening covers, unless a sign indicates otherwise. The importance of visible blades is further confirmed in NFPA 70E Article 120.1(3) when establishing an electrically safe work condition. As part of the procedure to establish a safe work condition, it states “Whenever possible, visually verify that all blades of the disconnecting devices are fully open or that drawout-type circuit breakers are withdrawn to the fully disconnected position”. This is a strong argument for using a switch with visible blades. Observing the switch blades through a viewing window is much safer than withdrawing a drawout-type circuit breaker. YouTube has numerous arc flash events involving drawout-type circuit breakers. Drawout-type circuit breakers may be the leading cause of NEC related arc flash events.

It should be noted that if switch blades are observed to be full open but the load conductors are unexpectedly confirmed to be energized, this is a violation NEC 406(C). If anyone comes across an installation where this is the case, they should insist that a permanent sign needs to be installed near the switch indicating the load conductors may remain energized by backfeed. Be proactive!

It will warn anyone working on this system in the future and may prevent an arc flash event.

Point No. 17, This proposal encourages working on energized equipment

Energy reduction for circuit breakers (NEC 240.87) allows an option of energy reducing maintenance switching. In theory, a maintenance mode may sound like a good feature, but if any worker thinks it is an alternative to de-energizing or allows for reduced
PPE requirements, then this feature is more harmful than good. With this feature activated, a worker can still be electrocuted if contact is made with electrical conductors. This feature provides a false sense of security. It may explain why the number of incidents increased in FY14 over FY13 (see Point No. 9).

Point No. 18, This proposal impacts products that do not have a risk problem

Thousands of manually-operated fused switches rated 1200 amp and above are used on 24 and 48 volt dc systems as battery disconnects. It is recognized throughout NFPA70E that there is little to no arc flash hazard at voltages below 50 volts. This proposal would put new requirements on these manually operated fusible switches. Clearly it would be a requirement that is not needed. The proposal should have an exception for applications below 50 volts.

Point No. 19, This proposal could significantly add to the number of arc flash events

Since 75% of the fusible switches 1200 amp and above are manually operated, these products will need to become shunt trip operated if fuses cannot be developed to comply with option (4) in the proposal. Manually operated switches are extremely reliable. They operate using an over-center spring which does not remain charged. A manual switch can be expected to operate decades after it is installed, with little to no maintenance. Shunt trip operator mechanisms have springs that remain charged when the switch is closed. Periodic exercise and proper lubrication is important, which means routine maintenance is important. Switch manufacturers typically recommend annual maintenance as a minimum on switches equipped with shunt trip mechanisms. Maintenance is an opportunity for an arc flash event because it requires opening doors or covers. The manual switch that performed reliably for 30 years without an arc flash hazard concern would evolve into thirty or more chances for an arc flash event if this proposal is adopted. Accordingly, this proposal has far-reaching effects that would dramatically increase the number of times a maintenance worker would be exposed to an arc flash hazard.

Point No. 20, Fuses are replaceable products

Fuses rated 1200 amp and above are non-renewable. If a fuse is called upon to function, it needs to be replaced. If a fusible switch has newer “arc reducing” fuses installed to meet the requirements of this proposal, and the fuses are called upon to function, what will insure that the replacement fuses will meet the arc reducing requirements? For Class L fuses, there are ten different types presently available from three major manufacturers. It could be that only a few of these types will be redesigned to meet the requirement of this proposal. If a facility needs to replace a fuse, they will likely be frantic to replace it as soon as possible. Remember, we are talking about 1200 amp & larger, so a big portion (if not all) of the facility will be down. They will use whatever fuses are in their storeroom, on the contractor’s truck, on the shelf at the nearest distributor, or whatever is available on eBay. Chances are the replacement fuse(s) will not be the same brand or type, and will not have the arc-reducing feature. Will newer “arc reducing” fuses need to incorporate rejection features to reject older fuses?

Point No. 21, Many types of fuses would be affected

While Class L fuses are the most popular for 1200 and above, there are many other fuses besides Class L. Boltswitch manufactures products that accept Class T fuses, semiconductor fuses, Form 101 fuses, BS88 fuses, and even older style Class M fuses. The Form 101 fuses are available in many dimensions (referred to as their “type” number) and in many voltages (500, 600, 700, 750, 1000 and 1500 volt), and usually mount in switches that are non-load-break by design. It is unlikely that many of these fuses (or the switches they mount in) can meet the new energy reducing requirements of this proposal. All of these different types of fuses are available and specified for a reason. Not all circuits are the same and need the same protection. Many of the switches accepting these switches are hook stick operated, and surely cannot be opened under load. This proposal is far too broad by including ALL fusible switches rated 1200 amp and larger.

Point No. 22, A proactive approach is better. This proposal is reactionary, not proactive.

If the electrical industry wants to get serious about reducing injuries caused by arc flash events, a pro-active approach would be to eliminate arc flash events from happening rather than trying to reduce the energy after an event happens. The first step should be to analyze electrical accidents. NEMA should form a committee to sit down with an OSHA representative for the purpose of reviewing electrical accidents. Problems cannot be solved unless they are understood. Proactive approaches should be developed to prevent accidents from happening, such as by increasing clearances between conductors or by adding barriers. This proposal cannot reduce the number of arc flash incidents because it is reactionary only. This proposal can influence a decision to work on energized equipment rather than shut it down and use lockout/tagout. If this proposal is adopted, the number of arc flash incidents can only be expected to increase. If someone is seriously hurt or electrocuted, a lawsuit will result. Anyone can be sued, the switch manufacturer, the fuse manufacturer, even the NFPA. If part of the claim is that the equipment had arc reducing features, defense of the lawsuit is quite different than defending a case where lockout/tagout procedures were violated. Circuit breaker manufacturers within NEMA wrote a white paper published in 2005 (and soon to be republished in 2015) titled Avoid Arc Flash Occurrences by Following Industry Standards. A complete paragraph from the document is as follows:

"The point is that the basic requirement, and it is a requirement, is to de-energize before working on equipment. The reason is that the hazard is removed by de-energizing. With careful planning, work can almost always be done with the equipment de-energized."

If this proposal goes forward, the proposal should include a warning, effectively saying "THE ENERGY REDUCING FEATURES ON THIS ASSEMBLY ARE NOT A SUBSTITUTE FOR FOLLOWING LOCKOUT/TAGOUT PROCEDURES. DO NOT WORK ON ENERGIZED EQUIPMENT". CMP 10 is taking a big chance with this proposal. As stated by circuit breaker manufacturers, work can almost always be done with the equipment de-energized. Lockout/tagout is a proactive approach that removes an electrical hazard. No action on the part of CMP 10 is better than taking the wrong action, which would be to adopt this proposal as is. Remember, the NEC is a minimum requirement. The minimum requirements for switches in the NEC (whether fusible or non-fusible) should be the ability to turn them off, lock them off, and verify they are off.
Point No. 23, The biggest problem . . . this protection does not belong on the service disconnect

You might think that I oppose this proposal as a switch manufacturer. Not true. The added components and shunt trip features will boost my sales. I oppose this proposal as a business owner. Let’s say a rooftop HVAC unit on my plant is not functioning. I’ll call the company that services our HVAC units. Each HVAC unit has a fused safety switch mounted at the unit. Each safety switch is fed from a CB in the building. Each CB is fed from the main switchboard, with a Boltswitch fusible service entrance switch. If troubleshooting on the HVAC unit is being done and an arc flash event happens, what product should clear the fault? My first choice is the fuses in the safety switch. My second choice is for the CB to clear the fault. That is what CB’s are designed to do. My absolute last choice is for a fuse in the service entrance switch to clear the fault. I have big problems if a main fuse functions. My entire plant will be down. If I am to follow NFPA70E, I first need to find and hire a qualified electrician. (Yes . . . even Boltswitch, the manufacturer of the service entrance switch, does not have a qualified electrician on staff to change a fuse under these conditions.) When the electrician arrives, I need to verify the electrician has appropriate PPE for any task he may need to perform. The electrician will need to assess the situation, repair and/or isolate any damage where the event happened, obtain & install new fuses in the service disconnect, verify the entire circuit is clear of faults, possibly schedule a shutdown with the utility so the contacts in the service disconnect can be inspected and dressed, and then follow a specific process before re-energizing, such as shutting down everything that was energized and re-energize as if the building was first being commissioned. Who knows how long it will be before my business is back up and running? There are many businesses and buildings similar to mine. If instead a fuse in the HVAC safety switch or the CB feeding it cleared the fault, I don’t have any of these problems. I merely have an HVAC unit that does not function and needs repair.

You do not want to be in a building if a fuse blows in the service disconnect. It does not matter if the service disconnect is a fused switch or fused circuit breaker. Every person in the building will have their day disrupted. It takes time to determine the problem and physically replace the fuse. If you are in a restaurant waiting for your meal, you may as well find another restaurant. If you are in a hotel room shaving, you will be shaving in the dark. If you are in a shopping mall, you may as well leave. The foremost purpose of fuses in the service disconnect is to clear a major fault such as closing into cables that are crossed. It does happen. Fuses in the service disconnect should not be the first line of response in an arc flash event. The service disconnect should not be required to open without any intentional delay. Article 230.95 understands this same concern in the event of a ground fault event. CMP 4 addresses the concern by allowing time delay and zone interlocking.

Boltswitch regularly sells 1200 amp fusible switches for use as the service disconnect on well-known restaurant chains nationwide. I am sure they do not have an electrical staff on duty that can deal with ANY situation concerning the service disconnect. The service disconnect is the only product in the building that cannot be completely de-energized by the occupants. Someone untrained and unfamiliar with electrical equipment will hastily take charge and will try to diagnose or rectify the problem. Most likely this person will not know what the letters PPE stand for. Service disconnects are often fed from the bottom. Changing fuses in a bottom-feed service disconnect requires work to be performed over live, unprotected incoming conductors. Most electrical contractors do not own the proper PPE for performing this work.

If this proposal is adopted, it should have an exception for fused switches used as the service disconnect. If someone thinks the features of this proposal would be good for the service disconnect, they should make a proposal for Article 230. Code Panel No. 4 should debate whether this is appropriate for service equipment. Hopefully they understand the hazards involved in changing fuses in the service disconnect, and realize the practice should be kept to a minimum.

As a switch manufacturer, I can attest with certainty that the service disconnect is the most ignored device in the building’s electrical system because it cannot be completely de-energized without a utility shutdown. Utilities request advance notice to schedule shutdowns, and typically charge fees. When this proposal was first being kicked around, I thought faster-acting fuses capable of responding quickly to arc flash events would be the perfect solution. I no longer think so. It is a bad situation for a fuse to open in a service disconnect, whether it is installed in a fusible switch or installed in a fusible circuit breaker. Changing a fuse (or fuses) in a service disconnect requires having replacement fuses on hand, it creates exposure to unprotected service conductors, it requires the use of tools within the energized cubicle, it requires handling bolts, washers & lock-washers while wearing PPE, and it takes time to physically perform the task. If the requirements of this proposal are enforced on service equipment, CMP 10 will be doing a disservice that will lead to serious injuries.

Conclusion

I realize that this proposal has enormous support. Everyone wants less injuries and safer workplaces. However, this proposal is not appropriate for all switches. Clearly, the requirements should not apply to systems below 50 volt, isolating switches, manual transfer switches and the like. It does not belong on many service disconnect switches. This proposal will not eliminate a single arc flash event because it is reactionary. It merely reduces arc energy. Lockout/tagout eliminates arc energy. Lockout/tagout should be an approved equivalent means because it is safer. This proposal is not appropriately placed in the code. Requirements for switches belong in Article 404 and the requirements for service disconnects belong in Article 230. If adopted, this proposal will create facility outages that should be handled by downstream devices, not the service disconnect. It will add maintenance needs to service equipment, which will only be neglected more-often than followed. Accordingly, as well intentioned as this proposal may be, it was not fully thought-out. It should be rejected.

If someone has to approach a switch to activate a “maintenance mode”, why can’t opening and locking off the same device be an approved equivalent means? A building owner has the right to prohibit working on energized equipment. A building owner can demand
the use of lockout/tagout procedures. If this proposal is adopted, Informational Note No. 4 should be added, stating the following:

Informational Note No. 4: An example of an approved equivalent means is a switch that has padlock provisions, visible blades, and is clearly marked “MANDATORY LOCKOUT/TAGOUT PROCEDURES REQUIRED IN ACCORDANCE WITH NFPA 70E”.

Adding this informational note hardly makes this proposal perfect, but it does make it more palatable. If added, I would accept this proposal.

Committee Statement
Committee Action: Rejected
Resolution: The SR created on 240.67 changes the focus of arc energy reduction from switches to fuses. The text now clearly applies to overcurrent protection provided by fuses, falling under the scope of Article 240 and within the purview of CMP10. Switches are not the only devices that could be used to provide the arc energy reduction. For example, fiber optics with an overcurrent relay could be utilized on the secondary side of a transformer to sense an arcing fault. A signal could then be sent to a vacuum interrupter or pyrotechnic fuses on the primary side of the transformer to open. Under that scenario, the switch on the secondary of the transformer is not involved in the arc energy reduction. The fiber optics with overcurrent relay in combination with a vacuum interrupter or pyrotechnic fuses would be examples of “An approved equivalent means” in list item 4. The 240.67 text includes requirements for fuses that are 1200 amperes or greater, not switches that are 1200 amperes or greater. Arc energy reduction techniques are not required for fuses less than 1200 amperes, where incident energies may be lower. For example, 400 ampere fuses, which are associated with lower incident energies than 1200 ampere fuses, might be installed in a 1200 ampere switch, without the need for additional arc energy reduction techniques. 240.67 does not preclude the use of smaller fuses. Arc energy reduction is not just designed for arc-flash incidents within the service entrance switch or circuit breaker, but rather for arc-flash incidents within the service entrance switchboard/switchgear, or within downstream equipment, such as a MCC where it is fed by a CB or fuses rated 1200 amps or greater. Exempting service entrance equipment from the arc energy reduction requirements would significantly reduce safety. Arc energy reduction techniques, including energy reducing maintenance switches, when used as part of an electrical safety program within the guidelines of NFPA 70E, have a proven track record of increasing worker safety. The intent of 240.67 is to reduce the arc energy to which a worker could be exposed. It does not negate the requirements in NFPA 70E or OSHA, which prohibit energized work except for two specific situations that are recognized as justified energized work (1) where additional hazards or increased risk are created if the equipment is de-energized and (2) infeasibility, meaning that the task to be performed requires the equipment to be energized, for example, where voltage testing is required. When a worker, following NFPA 70E and OSHA, is working on energized equipment, this new section will provide for a safer working environment, through the reduction of arc energy, in a manner that is similar to 240.87, where arc energy reduction techniques are required for 1200 amperes and greater circuit breakers.
Public Comment No. 608-NFPA 70-2015 [Section No. 240.67]

240.67 Arc Energy Reduction.
Where the ampere rating of the fusible switch is 1200 A or higher, 240.67(A) and (B) shall apply. This requirement shall become effective January 1, 2020.

(A) Documentation.
Documentation shall be available to those authorized to design, install, operate, or inspect the installation as to the location of the fusible switch(es).

(B) Method to Reduce Clearing Time.
One of the following shall be provided:

1. Differential relaying
2. Energy-reducing maintenance switching with local status indicator
3. Energy-reducing active arc flash mitigation system
4. A fuse that would open the circuit in 0.07-0.12 seconds or less, at or below the available arcing current
5. An approved equivalent means

Informational Note No. 1: An energy-reducing maintenance switch allows a worker to set a disconnect switch to reduce the clearing time while the worker is working within an arc-flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace, and then to set the disconnect switch back to a normal setting after the potentially hazardous work is complete.

Informational Note No. 2: An energy-reducing active arc flash mitigation system helps in reducing arcing duration in the electrical distribution system. No change in the disconnect switch or the settings of other devices is required during maintenance when a worker is working within an arc flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace.

Informational Note No. 3: IEEE 1584, IEEE Guide for performing Arc Flash Hazard Calculations, is one of the available methods that provide guidance in determining arcing current.

Statement of Problem and Substantiation for Public Comment
I have suggested under separate public comment that this proposal should be rejected. If the code panel does not agree and chooses to adopt this proposal, then the opening time for fuses should be changed to an appropriate level for switches.

Most fusible switches rated 1200 amp and above are NRTL Listed as Fused Power-Circuit Devices per UL977. The standard requires either bolted pressure contacts or butt contacts. Of the four present manufacturers of Fused Power Circuit Devices, three use bolted pressure contacts and one uses butt contacts. The fastest opening time for a new Fused Power-Circuit Device (in perfect condition) with bolted pressure contacts is 6 to 7 cycles. Age and lack of maintenance will result in longer opening times. The opening process typically involves unbolting at each end of the switch blades; followed by moving the switch blades toward the open position; followed by the engagement of arcing contacts; and finally followed by separation of the arcing contacts. Butt contacts merely need to separate. While bolted pressure contacts have an advantage of running very cool (truly a “green” feature), butt contacts have an advantage of opening faster. Bolted pressure contacts can never be as fast as butt contacts.

This proposal offers three methods for arc energy reduction by means of the switch contacts or one method by means of the fuse(s). Any of the three methods for most switches to clear the fault will take a minimum of 6-7 cycles (0.10-0.12 seconds) plus the reaction time of the arc sensing components. A total of 0.12 seconds is as fast as can be expected. Accordingly, the fuse clearing time in option (4) should be equal to the total clearing time in options (1), (2) or (3). If this proposal is adopted, the duration for the fuse to open in method (4) should be changed from 0.07 seconds or less to 0.12 seconds or less, a value that is appropriate for most switches.

Public Comment No. 610-NFPA 70-2015 [ Section No. 240.67 ]

240.67 Arc Energy Reduction.

Where the ampere rating of the fusible switch is 1200 A or higher, 240.67(A) and (B) shall apply. This requirement shall become effective January 1, 2020.

Exception 1: Not required on fused switches used as the service disconnect unless the device can be completely de-energized by the building occupants.

(A) Documentation.

Documentation shall be available to those authorized to design, install, operate, or inspect the installation as to the location of the fusible switch(es).

(B) Method to Reduce Clearing Time.

One of the following shall be provided:

1. Differential relaying
2. Energy-reducing maintenance switching with local status indicator
3. Energy-reducing active arc flash mitigation system
4. A fuse that would open the circuit in 0.07 seconds or less, at or below the available arcing current
5. An approved equivalent means

Informational Note No. 1: An energy-reducing maintenance switch allows a worker to set a disconnect switch to reduce the clearing time while the worker is working within an arc-flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace, and then to set the disconnect switch back to a normal setting after the potentially hazardous work is complete.

Informational Note No. 2: An energy-reducing active arc flash mitigation system helps in reducing arcing duration in the electrical distribution system. No change in the disconnect switch or the settings of other devices is required during maintenance when a worker is working within an arc flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace.

Informational Note No. 3: IEEE 1584, IEEE Guide for performing Arc Flash Hazard Calculations, is one of the available methods that provide guidance in determining arcing current.

Statement of Problem and Substantiation for Public Comment

I have suggested under separate public comment that this proposal should be rejected. If the code panel does not agree and chooses to adopt this proposal, fused switches rated 1200 amp and above will open more often, and will be opening under fault conditions. Fuses will also open more often if, as a result of this requirement, fuses are redesigned to respond to arc flash events. These are facts, since this proposal does nothing to prevent an arc flash event from happening in the first place. If after adoption of this proposal switches and/or fuses do not open more often, then adoption of this proposal will have served no useful purpose.

When a switch opens under fault conditions, maintenance is required before re-energizing. Unlike circuit breakers, switch standards allow for maintenance after each test operation under fault conditions. Accordingly, maintenance is expected any time after a switch opens under fault conditions. Proper maintenance is essential for properly functioning switches. Similarly, if a fuse opens, the fuse must be replaced. Replacing a fuse can only be done manually by humans with tools.

NFPA70E, 130.6 (M) addresses “Reclosing Circuits after Protective Device Operation”. It states “After a circuit is de-energized by the automatic operation of a circuit protective device, the circuit shall not be manually reenergized until it has been determined that the equipment and circuit can be safely energized. The repetitive manual reclosing of circuit breakers or reenergizing circuits through replaced fuses shall be prohibited.” This requirement substantiates the need for maintenance after an arc flash event results in a switch automatically opening.

If the switch happens to be is a service disconnect, this presents a unique problem. The contacts on a service disconnect cannot be serviced unless the building owners have a disconnect feeding the primary side of the transformer or a utility shutdown is arranged. Utility shutdowns require scheduling and a fee.

There are many causes of arc flash events. Human causes are the reason for this proposal. However, most arc flash events do not involve humans or human safety. Common causes are water entering equipment, windblown dust, rodents, loose wire connections, aging insulation, and voltage spikes. The consequences are generally not catastrophic. A downstream fuse or circuit breaker feeding the particular equipment usually opens. The rest of the building remains energized, which is usually desired.

In cases where a service disconnect switch cannot be completely de-energized by the building occupants, consideration should be given concerning the events for re-energizing the building. The service disconnect switch will need maintenance. Fuses in the service disconnect will need to be checked and may need to be replaced. A Utility shut-down usually puts humans (utility employees) in danger.
of an arc flash event. (If a utility worker is wearing PPE, you can bet he is wearing the PPE for a reason.) If the fuses need to be checked or replaced, a human may be asked to work with tools in an energized service disconnect compartment. A human is now in danger of an arc flash event near extremely dangerous service entrance conductors. If this proposal is adopted, this will be the result even when the initial arc flash event did not involve humans or human safety.

It should also be recognized that in new installations, fuses are often installed in service entrance equipment before the equipment ships to the jobsite, when there is no electrical hazard. If fuses in a service disconnect respond more frequently as a result of the new requirement, there should be serious concern about replacing these fuses, particularly if the service conductors are bottom fed (which is very common). Humans will be asked more often to work with tools over energized service conductors. This proposal creates opportunities for extremely serious arc flash events that never existed before. If adoption of this proposal results in human injuries that otherwise would not have happened, who is to blame?

In summary, any maintenance in the service entrance compartment poses unique hazards. Creating maintenance work in this compartment should be avoided, particularly if the building occupants cannot completely de-energize the incoming conductors. Recommended maintenance is usually ignored on service equipment as it is. Merely adding a shunt trip to what was a manual switch adds maintenance. If a service disconnect switch or its fuses function more frequently as a result of this proposal (which they will), more work in the service disconnect compartment will result. Arc energy reduction features should not be mandatory on a service disconnect switch that cannot be completely de-energized by the building occupants.

Committee Statement

Committee Action: Rejected
Resolution: Arc energy reduction does not apply to only service entrance switches or circuit breakers, it also applies within the service entrance switchboard/switchgear, or within downstream equipment, such as a MCC where it is fed by a CB or fuses rated 1200 amps or greater. Exempting service entrance equipment from the arc energy reduction requirements would significantly reduce safety.
240.67 Arc Energy Reduction.

Where the ampere rating of the fusible switch is 1200 A or higher, 240.67(A) and (B) shall apply. This requirement shall become effective January 1, 2020.

(A) Documentation.

Documentation shall be available to those authorized to design, install, operate, or inspect the installation as to the location of the fusible switch(es).

(B) Method to Reduce Clearing Time.

One of the following shall be provided:

1. Differential relaying
2. Energy-reducing maintenance switching with local status indicator
3. Energy-reducing active arc flash mitigation system
4. A fuse that would open the circuit in 0.07 seconds or less, at or below the available arcing current
5. An approved equivalent means

Informational Note No. 1: An energy-reducing maintenance switch allows a worker to set a disconnect switch to reduce the clearing time while the worker is working within an arc-flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace, and then to set the disconnect switch back to a normal setting after the potentially hazardous work is complete.

Informational Note No. 2: An energy-reducing active arc flash mitigation system helps in reducing arcing duration in the electrical distribution system. No change in the disconnect switch or the settings of other devices is required during maintenance when a worker is working within an arc flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace.

Informational Note No. 3: IEEE 1584, IEEE Guide for performing Arc Flash Hazard Calculations, is one of the available methods that provide guidance in determining arcing current.

Statement of Problem and Substantiation for Public Comment

I have suggested under separate public comment that this proposal should be rejected. If the code panel does not agree and chooses to adopt this proposal, then the word “fusible” in the first sentence should be changed to “fused”.

There is a difference between a fusible switch and a fused switch. Boltswitch manufactures and sells “dummy fuses” for installations where overcurrent protection is not required. A fusible switch equipped with dummy fuses is the same as a non-fusible switch. This proposal is not intended to cover non-fusible switches. (If it is intended to cover non-fusible switches, then the proposal does not belong in Article 240.)

The products mostly affected by this proposal are called “Fused Power-Circuit Devices”, which coincides with the title of the UL standard (UL977). The standard is not called “Fusible Power-Circuit Devices”.

Committee Statement

Committee Action: Rejected
| Resolution: | See the Second Revision on 240.67. This SR changes the focus of arc energy reduction in this section from switches to fuses. |
240.67 Arc Energy Reduction.
Where the ampere rating of the fusible switch is 1200 A or higher, 240.67(A) and (B) shall apply. This requirement shall become effective January 1, 2020.

(A) Documentation.
Documentation shall be available to those authorized to design, install, operate, or inspect the installation as to the location of the fusible switch(es).

(B) Method to Reduce Clearing Time.
One of the following shall be provided:

1. Differential relaying
2. Energy-reducing maintenance switching with local status indicator
3. Energy-reducing active arc flash mitigation system
4. A fuse that would open the circuit in 0.07 seconds or less, at or below the available arcing current
5. An approved equivalent means

Informational Note No. 1: An energy-reducing maintenance switch allows a worker to set a disconnect switch to reduce the clearing time while the worker is working within an arc-flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace, and then to set the disconnect switch back to a normal setting after the potentially hazardous work is complete.

Informational Note No. 2: An energy-reducing active arc flash mitigation system helps in reducing arcing duration in the electrical distribution system. No change in the disconnect switch or the settings of other devices is required during maintenance when a worker is working within an arc flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace.

Informational Note No. 3: IEEE 1584, IEEE Guide for performing Arc Flash Hazard Calculations, is one of the available methods that provide guidance in determining arcing current.

Statement of Problem and Substantiation for Public Comment
I have suggested under separate public comment that this proposal should be rejected. If the code panel does not agree and chooses to adopt this proposal, then the term “or below” in Method (4) should be deleted.

The available arcing current is a calculated value for a given point in the electrical system. If a fuse is intended to operate within a prescribed period of time at a calculated current value, the fuse cannot be expected to operate within that prescribed time at a lesser current value. The term “or below” should not be part of the requirement.

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-2702-NFPA 70-2015
Statement: The focus of arc energy reduction is modified for clarity and references “fuses” not “switches,” removing all potential confusion about “fusible switches” versus “fused switches” or transfer switches.
This requirement addresses “arc energy reduction” and is properly located in Article 240 and under the purview of CMP 10.

The revised text now clearly applies to overcurrent protection provided by fuses. Similar requirements exist in 240.87 for “arc energy reduction” where the overcurrent devices are circuit breakers.
240.67.  Arc Energy Reduction.
Where the ampere rating of the fusible switch is 1200 A or higher, 240.67(A) and (B) shall apply. This requirement shall become effective January 1, 2020.

(A)  Documentation.
Documentation shall be available to those authorized to design, install, operate, or inspect the installation as to the location of the fusible switch(es).

(B)  Method to Reduce Clearing Time.
One of the following shall be provided:

(1)  Differential relaying
(2)  Energy-reducing maintenance switching with local status indicator
(3)  Energy-reducing active arc flash mitigation system
(4)  A fuse that would open the circuit in 0.07 seconds or less, at or below the available arcing current
(5)  An approved equivalent means

Informational Note No. 1: An energy-reducing maintenance switch allows a worker to set a disconnect switch to reduce the clearing time while the worker is working within an arc-flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace, and then to set the disconnect switch back to a normal setting after the potentially hazardous work is complete.

Informational Note No. 2: An energy-reducing active arc flash mitigation system helps in reducing arcing duration in the electrical distribution system. No change in the disconnect switch or the settings of other devices is required during maintenance when a worker is working within an arc flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace.

Informational Note No. 3: IEEE 1584, IEEE Guide for performing Arc Flash Hazard Calculations, is one of the available methods that provide guidance in determining arcing current.

Statement of Problem and Substantiation for Public Comment
By adding a new Section 240.67 located under Part IV titled "Cartridge Fuses and Fuseholders" will lead to major confusion and enforcement will not be uniform. The requirements for fusible switches are appropriately covered in Article 404. Article 240 pertains to overcurrent and not the operation of switches. When it is intended to apply to service disconnects then additional language should appear in Article 230.

The change does not recognize that there are hundreds of manually operated fusible switches functioning every day safely. If this change continues to be accepted it will prevent the replacement of manually operated switches in existing facilities without major expensive design changes.

If the proponent's comment that "energy reduction incidents could also be utilized with fusible switches" is not sufficient substantiation for a change as major as this is.

If the proponent believes this proposed requirement should be placed on switches similar to circuit breakers then proper substantiation should be provided and the change should be submitted to Article 404 with added provisions for allowing the continued use of manually operated switches where appropriately designed.

Committee Statement

Resolution: The SR created on 240.67 changes the focus of arc energy reduction from switches to fuses. The text now clearly applies to overcurrent protection provided by fuses, falling under the scope of Article 240 and within the purview of CMP10. Switches are not the only devices that could be used to provide the arc energy reduction. For example, fiber optics with an overcurrent relay could be utilized on the secondary side of a transformer to sense an arcing fault. A signal could then be sent to a vacuum interrupter or pyrotechnic fuses on the primary side of the transformer to open. Under that scenario, the switch on the secondary of the transformer is not involved in the arc energy reduction. The fiber optics with overcurrent relay in combination with a vacuum interrupter or pyrotechnic fuses would be examples of “An approved equivalent means” in list item 4. The 240.67 text includes requirements for fuses that are 1200 amperes or greater, not switches that are 1200 amperes or greater. Arc energy reduction techniques are not required for fuses less than 1200 amperes, where incident energies may be lower. For example, 400 ampere fuses, which are associated with lower incident energies than 1200 ampere fuses, might be installed in a 1200 ampere switch, without the need for additional arc energy reduction techniques. 240.67 does not preclude the use of smaller fuses. Arc energy reduction is not just designed for arc-flash incidents within the service entrance switch or circuit breaker, but rather for arc-flash incidents within the service entrance switchboard/switchgear, or within downstream equipment, such as a MCC where it is fed by a CB or fuses rated 1200 amps or greater. Exempting service entrance equipment from the arc energy reduction requirements would significantly reduce safety. Arc energy reduction techniques, including energy reducing maintenance switches, when used as part of an electrical safety program within the guidelines of NFPA 70E, have a proven track record of increasing worker safety. The intent of 240.67 is to reduce the arc energy to which a worker could be exposed. It does not negate the requirements in NFPA 70E or OSHA, which prohibit energized work except for two specific situations that are recognized as justified energized work (1) where additional hazards or increased risk are created if the equipment is de-energized and (2) infeasibility, meaning that the task to be performed requires the equipment to be energized, for example, where voltage testing is required. When a worker, following NFPA 70E and OSHA, is working on energized equipment, this new section will provide for a safer working environment, through the reduction of arc energy, in a manner that is similar to 240.87, where arc energy reduction techniques are required for 1200 ampere and greater circuit breakers.
240.67 - Arc Energy Reduction.

Where the ampere rating of the fusible switch is 1200 A or higher, 240.67(A) and (B) shall apply. This requirement shall become effective January 1, 2020.

(A) - Documentation.

Documentation shall be available to those authorized to design, install, operate, or inspect the installation as to the location of the fusible switch(es).

(B) - Method to Reduce Clearing Time.

One of the following shall be provided:

1. Differential relaying
2. Energy-reducing maintenance switching with local status indicator
3. Energy-reducing active arc flash mitigation system
4. A fuse that would open the circuit in 0.07 seconds or less, at or below the available arcing current
5. An approved equivalent means

Informational Note No. 1: An energy-reducing maintenance switch allows a worker to set a disconnect switch to reduce the clearing time while the worker is working within an arc-flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace, and then to set the disconnect switch back to a normal setting after the potentially hazardous work is complete.

Informational Note No. 2: An energy-reducing active arc flash mitigation system helps in reducing arcing duration in the electrical distribution system. No change in the disconnect switch or the settings of other devices is required during maintenance when a worker is working within an arc flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace.

Informational Note No. 3: IEEE 1584, IEEE Guide for performing Arc Flash Hazard Calculations, is one of the available methods that provide guidance in determining arcing current.

Statement of Problem and Substantiation for Public Comment

Public Comment for First Revision No. 2707-NFPA 70-2015 [New Section 240.67]

Submitted by: Peter Walsh, Mersen, USA

This document is public comment for a proposal to add 240.67 "Arc Energy Reduction" to NFPA70-2017 (the NEC). The substantiation for the proposal is that the benefits of arc energy reduction requirements for circuit breakers in NEC 240.87 have been well established and thus should be added to the requirements for fusible switches. Mersen supports reducing arc flash energy. It is important that the proposal promotes safety and is appropriate for switches; is appropriately placed in the NEC; and does not conflict with other sections of the NEC.

The proposal is not appropriate for switches

Most switches are manually operated. Three out of every four fusible switches rated 1200 amp and above are manually operated. Manually operated switches are important components for safe, electrical systems. This proposal could eliminate all manually operated fusible switches rated 1200 amp and above if fuses are unable to meet the fuse requirements (option 4) of this proposal.

Many switches were never intended to be anything but manually operated. Fusible manual transfer switches, double throw switches and bypass isolation switches rated 1200 amp and above are commonly used in applications such as standby systems. These switches were never intended to have other than a manual operating means. If fuses that open under arc fault conditions set forth in this proposal are not properly selected, these manually operated switch products will require a means to open automatically, which goes against the product definition. Automatic transfer switches do not function without proper care. They require routine testing and maintenance. Manually-operated switches are extremely dependable.

The proposal requires changing the definition of a switch. There are five definitions used in the NEC and NFPA 70E that apply to switches rated 1200 amp and above. Each of the definitions applies to fusible or non-fusible switches. The definitions are as follows:

1.) “Switching Device” is defined in the NEC and NFPA70E as “A device designed to close, open, or both, one or more electric circuits”.
2.) “Switch, Bypass Isolation” is defined in the NEC as “A manually operated device used in conjunction with a transfer switch to provide a means of directly connecting load conductors to a power source and of disconnecting the transfer switch”.
3.) “Switch, General-Use” is defined in the NEC as “A switch intended for use in general distribution and branch circuits. It is rated in amperes, and it is capable of interrupting its rated current at its rated voltage”.
4.) “Switch, Isolating” is defined in the NEC as “A switch intended for isolating an electrical circuit from the
source of power. It has no interrupting rating, and it is intended to be operated only after the circuit has been opened by some other means.

5) “Switch, Transfer” is defined in the NEC as “An automatic or non-automatic device for transferring one or more load conductor connections from one power source to another.

By any of the definitions, a switch (fusible or non-fusible) is not an overcurrent protection device and it is not required to open a circuit automatically.

Four of the five definitions do not require the switch to be capable of opening under load. Only a “Switch, General-Use” is required to be capable of opening the circuit under load. If this proposal is adopted, all five of these types of switches rated 1200 amp and above will be required to be load break and also be capable of interrupting a fault current.

Thousands of manually-operated fused switches rated 1200 amp and above are used on 24 and 48 volt dc systems as battery disconnects. It is recognized throughout NFPA70E that there is little to no arc flash hazard at voltages below 50 volts. This proposal would put new requirements on these manually operated fusible switches. The proposal should have an exception for applications below 50 volts.

The proposal is in the wrong location, switches are described elsewhere in the NEC

Switches are presently addressed in Article 404 of the NEC. If adopted, some requirements for switches would be in Article 404 and some requirements would be in Article 240. NEC 404.1 provides the scope for switches in the NEC. It is very clear. Only switches rated above 1000 volt are to be covered elsewhere in the NEC. This is not the case with the proposal and would require changes in Section 404.1.

The requirements conflict with other parts of the NEC

NEC 404.13(A) states isolating switches rated over 1200 amp shall not be opened under load. Isolation switches can be and often are fusible switches. This proposal would require these same switches to open a fault current automatically if fuses are not installed to comply with option (4). Accordingly, the proposal directly conflicts with the requirements of NEC 404.13(A).

The term “fusible switch” is not defined. Many “fusible switches” have copper bars installed in the fuse gap, commonly called dummy fuses. Would a “fusible switch” with dummy fuses installed be subject to the requirements of this proposal? I would think the answer is no, since the assembly would be the same as a non-fusible switch. But technically the switch itself is still a “fusible switch”.

430.90 in the NEC is titled “Combination Fuseholder and Switch as Controller”. If a fuseholder (with fuses installed) and a non-fusible switch are combined, would the requirements of this proposal apply? There would be three separately listed products involved, and none of them would be a “fusible switch”. Changing the term “fusible switch” to “fused switch” may add clarity to this situation. Most people would consider the combination to be a “fused switch”.

Safety

An important safety feature on switches is that they can be padlocked in the ON position. Switches are often mounted outside. Most Firefighters prefer to have switches mounted outside. Some jurisdictions even require the service disconnect to be located outside however only manually operated switches can be padlocked in the ON position. Shunt trip operated switches or any circuit breaker cannot be padlocked in the ON position. This proposal will force many manually operated switches to become shunt trip operated, which means they can no longer be padlocked “ON”.

Switches can be equipped with key interlocks to lock in the OFF position, ON position, or both. Key interlock schemes are used to ensure that each product in the system is in a prescribed position before another action can be taken. Key interlocks may have auxiliary contacts and solenoid releases, and can be mounted in many ways, including on doors and panels of electrical equipment. Key interlock schemes can be used to prevent access to energized electrical components. The point is that key interlocks are used on switches in a proactive manner to prevent the occurrence of an arc flash event. Often the switches are manually operated and key interlocked in the ON position to prevent opening the switch under load. This proposal will adversely impact these proactive schemes. Shunt trip operated switches and circuit breakers cannot have key interlocks for locking in the ON position.

Needed Exceptions

This proposal lacks key exceptions. The first is an exception for applications with the working distance having not over 8 Cal/cm2. Under this level the hazard is compatible with normal Category 2 arc rated PPE.

The second needed exception is in industrial processes. Sometimes they need selective coordination but this proposal would cause additional hazards such as considered in 240.12.

The third exception is for a switch with ampere ratings below 1200 amps. Frequently 1200 amp switch is required for shunt trip or other functionality independent of the service entrance rating. Fuses can be sized at 400A, 600A, 800A, and 1000A and still fit into the 1200 amp fused switch. A 400 amp switch does not have the same communications and trips available as a 1200 amp.

Conclusion

As the reader can see, the proposal does not promote safety, it is not appropriate for switches or fuses, it conflicts with other sections of the NEC, and it is in the wrong place. It is not good code and should be rejected

Committee Statement

Committee Action: Rejected

Resolution: The SR created on 240.67 changes the focus of arc energy reduction from switches to fuses. The text now clearly applies to overcurrent protection provided by fuses, falling under the scope of Article 240 and within the purview of CMP10. Switches are not the only devices that could be used to provide the arc energy reduction. For example, fiber optics with an overcurrent relay could be utilized on the secondary side of a transformer to sense an arcing fault. A signal could then be sent to a vacuum interrupter or pyrotechnic fuses on the primary side of the transformer to open. Under that scenario, the switch on the secondary of the transformer is not involved in the arc energy reduction. The fiber optics with overcurrent relay in combination with a vacuum interrupter or pyrotechnic fuses would be examples of “An approved equivalent means” in list item 4. The 240.67 text includes requirements for fuses that are 1200 amperes or greater, not switches that are 1200 amperes or greater. Arc energy reduction techniques are not required for fuses less than 1200 amperes, where incident energies may be lower. For example, 400 ampere fuses, which are associated with lower incident energies than 1200 ampere fuses, might be installed in a 1200 ampere switch, without the need for additional arc energy reduction techniques. 240.67 does not preclude the use of smaller fuses. Arc energy reduction is not just designed for arc-flash incidents within the service entrance switch or circuit breaker, but rather for arc-flash incidents within the service entrance switchboard-switchgear, or within downstream equipment, such as a MCC where it is fed by a CB or fuses rated 1200 amps or greater. Exempting service entrance equipment from the arc energy reduction requirements would significantly reduce safety. Arc energy reduction techniques, including energy reducing maintenance switches, when used as part of an electrical safety program within the guidelines of NFPA 70E, have a proven track record of increasing worker safety. The intent of 240.67 is to reduce the arc energy to which a worker could be exposed. It does not negate the requirements in NFPA 70E or OSHA, which prohibit energized work except for two specific situations that are recognized as justified energized work (1) where additional hazards or increased risk are created if the equipment is de-energized and (2) infeasibility, meaning that the task to be performed requires the equipment to be energized, for example, where voltage testing is required. When a worker, following NFPA 70E and OSHA, is working on energized equipment, this new section will provide for a safer working environment, through the reduction of arc energy, in a manner that is similar to 240.87, where arc energy reduction techniques are required for 1200 ampere and greater circuit breakers.
Public Comment No. 1365-NFPA 70-2015 [Section No. 240.67 [Excluding any Sub-Sections]]

Where the ampere rating of the fusible switch is 1200 A or higher, 240.67(A) and (B) shall apply. This requirement shall become effective January 1, 2020.

Exception: The requirements of 240.67(A) and (B) do not apply to fusible transfer switches rated at 1200 A or higher.

Statement of Problem and Substantiation for Public Comment

Incident energy reduction techniques will generally already be utilized upstream of the transfer switch.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-2702-NFPA 70-2015
Statement: The focus of arc energy reduction is modified for clarity and references “fuses” not “switches,” removing all potential confusion about “fusible switches” versus “fused switches” or transfer switches.

This requirement addresses “arc energy reduction” and is properly located in Article 240 and under the purview of CMP 10.

The revised text now clearly applies to overcurrent protection provided by fuses. Similar requirements exist in 240.87 for “arc energy reduction” where the overcurrent devices are circuit breakers.
Where the ampere rating of the fusible fused switch capable of opening automatically is 1200 A or higher, 240.67(A) and (B) shall apply. This requirement shall become effective January 1, 2020.

Statement of Problem and Substantiation for Public Comment

Some switches by definition are not capable or allowed to open automatically such as an isolating switch or a knife switch.

Submittal Date: Mon Sep 21 14:42:39 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The extended effective date is necessary to allow for equipment design and manufacturing changes. The NEC currently allows for the installation of these arc reduction techniques.
(B) Method to Reduce Clearing Time.

One. Unless downstream incident energy at the working distance is documented to be 8 cal/cm² or lower, one of the following shall be provided:

1. Differential relaying
2. Energy-reducing maintenance switching with local status indicator
3. Energy-reducing active arc flash mitigation system
4. A fuse that would open the circuit in 0.07 seconds or less, at or below the available arcing current
5. An approved equivalent means

The requirements of 240.67(B) shall not be required to apply to fusible switches serving continuous industrial processes where a lack of protective device coordination will introduce greater or other hazards.

Informational Note No. 1: An energy-reducing maintenance switch allows a worker to set a disconnect switch to reduce the clearing time while the worker is working within an arc-flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace, and then to set the disconnect switch back to a normal setting after the potentially hazardous work is complete.

Informational Note No. 2: An energy-reducing active arc flash mitigation system helps in reducing arcing duration in the electrical distribution system. No change in the disconnect switch or the settings of other devices is required during maintenance when a worker is working within an arc flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace.

Informational Note No. 3: IEEE 1584, IEEE Guide for Performing Arc Flash Hazard Calculations, is one of the available methods that provide guidance in determining arcing current.

Statement of Problem and Substantiation for Public Comment

First as proposed in PI 1704 for 240.87 in the first draft stage, methods to reduce clearing time should not be required by the NEC for installations where the calculated incident energy at the working distance is 8 cal/cm² or less. Required PPE for this energy level is consistent with the reduced PPE level that will be required after 240.67-approved methods to reduce clearing time are applied to some installations, and consistent with what is needed for some installations that would not fall under 240.67. It is common in many workplaces to provide 8 cal/cm² clothing as daily wear. Second as proposed in PI 1764 in the first draft stage for 240.87, there should be an exception to these requirements where the fusible switch serves continuous industrial processes where a lack of protective device coordination will introduce greater or other hazards. All of the measures that could be cost-effectively provided for loads served by an outgoing fusible switch would introduce some level of protective device miscoordination. Qualified industrial users should be allowed to appropriately manage the full spectrum of hazards, which they could do via the proposed exception.

Committee Statement

Committee Action: Rejected
Resolution: No technical justification has been provided for a permitted exposure threshold of an incident energy equal to 8 cal/cm² when the arc energy reduction techniques may be able to reduce the arc energy to a much lower value. An exemption for industrial processes is unnecessary because arc energy reduction techniques are available. CMP 10 requests that the
NFPA Research Foundation initiate a study to determine what, if any, incident energy level would be an acceptable exposure level in the installation code, NFPA 70.
Public Comment No. 575-NFPA 70-2015 [Section No. 240.67(B)]

(B) Method to Reduce Clearing Time.
One of the following shall be provided:

1. Differential relaying
2. Energy-reducing maintenance switching with local status indicator
3. Energy-reducing active arc flash mitigation system
4. A fuse that would open the circuit in 0.07 seconds or less, at or below, the available arcing current
5. An approved equivalent means

Informational Note No. 1: An energy-reducing maintenance switch allows a worker to set a disconnect switch to reduce the clearing time while the worker is working within an arc-flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace, and then to set the disconnect switch back to a normal setting after the potentially hazardous work is complete.

Informational Note No. 2: An energy-reducing active arc flash mitigation system helps in reducing arcing duration in the electrical distribution system. No change in the disconnect switch or the settings of other devices is required during maintenance when a worker is working within an arc flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace.

Statement: The focus of arc energy reduction is modified for clarity and references "fuses" not "switches," removing all potential confusion about "fusible switches" versus "fused switches" or transfer switches.

This requirement addresses "arc energy reduction" and is properly located in Article 240 and under the purview of CMP 10.

The revised text now clearly applies to overcurrent protection provided by fuses. Similar requirements exist in 240.87 for "arc energy reduction" where the overcurrent devices are circuit breakers.
Section 240.83(A)

Durable and Visible.

Circuit breakers shall be marked with their ampere rating in a manner that will be durable and visible after installation. Such marking shall be permitted to be made visible by removal of a trim or cover.

Statement of Problem and Substantiation for Public Comment

The circuit breaker label is vital in determining both code compliance and trip characteristics. For purposes of determining arc flash incident energy levels, the exact circuit breaker manufacturer and model must be determined, and the engineer or inspector should not be burdened or subjected to unsafe tasks such as removing trim cover on energized systems. Rejecting this proposed code change on the basis of not having enough room or added cost should be classified as criminal neglect should a person be harmed.

Submittal Date: Mon Jun 22 16:43:10 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The submitter has not substantiated a problem with existing code requirements. It is not practical to require that these and other markings be provided in an unobstructed location that can be easily and safely read by an individual making a survey of energized equipment. Individuals performing an incident energy analysis on an existing system must follow all applicable OSHA regulations and the industry standard for electrical safety in the workplace, NFPA 70E.
(B) Method to Reduce Clearing Time.

One of the following means shall be provided:

(1) Zone-selective interlocking
(2) Differential relaying
(3) Energy-reducing maintenance switching with local status indicator
(4) Energy-reducing active arc flash mitigation system
(5) An instantaneous trip setting that is less than the available arcing current greater than the maximum instantaneous trip setting, if adjustable
(6) An instantaneous override that is less than the available arcing current
(7) An approved equivalent means

Informational Note No. 1: An energy-reducing maintenance switch allows a worker to set a circuit breaker trip unit to “no intentional delay” to reduce the clearing time while the worker is working within an arc-flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace, and then to set the trip unit back to a normal setting after the potentially hazardous work is complete.

Informational Note No. 2: An energy-reducing active arc flash mitigation system helps in reducing arcing duration in the electrical distribution system. No change in the circuit breaker or the settings of other devices is required during maintenance when a worker is working within an arc flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace.

Informational Note No. 3: An instantaneous trip is a function that causes a circuit breaker to trip with no intentional delay when currents exceed the instantaneous trip setting or current level. If arcing currents are above the instantaneous trip level, the circuit breaker will trip in the minimum possible time.

Informational Note No. 4: IEEE 1584–2002, IEEE Guide forPerforming Arc Flash Hazard Calculations, is one of the available methods that provide guidance in determining arcing current.

Statement of Problem and Substantiation for Public Comment

As accepted by FR 2706, someone could avoid using one of the incident energy reduction methods by turning down the instantaneous trip, then after final inspection, turning up the instantaneous trip to achieve selective coordination. If accepted, this public comment would assure that the intent of incident energy reduction is not circumvented.

Committee Statement

Committee Action: Rejected
Resolution: The adjustment of a circuit breaker’s instantaneous trip to a setting below the arcing current is a proven method to reduce clearing time and therefore incident energy. No substantiation has been provided to indicate that injuries have occurred because an instantaneous trip was adjusted to a setting that was higher than the arcing current.
Method to Reduce Clearing Time.

One of the following means shall be provided:

1. Zone-selective interlocking
2. Differential relaying
3. Energy-reducing maintenance switching with local status indicator
4. Energy-reducing active arc flash mitigation system
5. An instantaneous trip setting that is less than the available arcing current or an adjustable instantaneous trip setting that is set to minimum and is not changed
6. An instantaneous override that is less than the available arcing current
7. An approved equivalent means

Informational Note No. 1: An energy-reducing maintenance switch allows a worker to set a circuit breaker trip unit to "no intentional delay" to reduce the clearing time while the worker is working within an arc-flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace, and then to set the trip unit back to a normal setting after the potentially hazardous work is complete.

Informational Note No. 2: An energy-reducing active arc flash mitigation system helps in reducing arcing duration in the electrical distribution system. No change in the circuit breaker or the settings of other devices is required during maintenance when a worker is working within an arc flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace.

Informational Note No. 3: An instantaneous trip is a function that causes a circuit breaker to trip with no intentional delay when currents exceed the instantaneous trip setting or current level. If arcing currents are above the instantaneous trip level, the circuit breaker will trip in the minimum possible time.

Informational Note No. 4: IEEE 1584–2002, IEEE Guide for Performing Arc Flash Hazard Calculations, is one of the available methods that provide guidance in determining arcing current.

Statement of Problem and Substantiation for Public Comment

Items (5) and (6) are effective ways reduce arc flash energy as stated by the committee and are a valuable addition to 240.87. The committee does an excellent job identifying that instantaneous trips may be as fast or faster as the other means stated. The committee is also correct in identifying that the trip setting must be below the arcing current. When the trip setting is low the instantaneous trip will operate and provide better protection.

Maintenance switches remove intentional delays from instantaneous trips and may also reduce the trip settings. The end result is that the circuit breaker with the maintenance switch activated acts identically to any circuit breaker that has an instantaneous trip that is already set to minimum. This proposed change recognizes that either a circuit breaker with a maintenance switch or one with an instantaneous trip set to minimum provides equivalent arc flash protection. This also provides a way to apply an effective protection means without performing an arc flash study. None of the other means require an arc flash study in order to be implemented; this proposal aligns the use of an instantaneous trip with the other allowed means.

<tbody>
<tr>
<td>Resolution:</td>
<td>When the available arcing current is greater than the instantaneous trip, no further action is required.</td>
</tr>
</tbody>
</table>
(B) Method to Reduce Clearing Time.

One, unless downstream incident energy at the working distance is documented to be 8 cal/cm² or lower, one of the following means shall be provided:

1. Zone-selective interlocking
2. Differential relaying
3. Energy-reducing maintenance switching with local status indicator
4. Energy-reducing active arc flash mitigation system
5. An instantaneous trip setting that is less than the available arcing current
6. An instantaneous override that is less than the available arcing current
7. An approved equivalent means

The requirements of 240.87(B) shall not be required to apply to circuit breakers serving continuous industrial processes where a lack of protective device coordination will introduce greater or other hazards

Informational Note No. 1: An energy-reducing maintenance switch allows a worker to set a circuit breaker trip unit to "no intentional delay" to reduce the clearing time while the worker is working within an arc-flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace, and then to set the trip unit back to a normal setting after the potentially hazardous work is complete.

Informational Note No. 2: An energy-reducing active arc flash mitigation system helps in reducing arcing duration in the electrical distribution system. No change in the circuit breaker or the settings of other devices is required during maintenance when a worker is working within an arc flash boundary as defined in NFPA 70E-2015, Standard for Electrical Safety in the Workplace.

Informational Note No. 3: An instantaneous trip is a function that causes a circuit breaker to trip with no intentional delay when currents exceed the instantaneous trip setting or current level. If arcing currents are above the instantaneous trip level, the circuit breaker will trip in the minimum possible time.

Informational Note No. 4: IEEE 1584-2002, IEEE Guide for Performing Arc Flash Hazard Calculations, is one of the available methods that provide guidance in determining arcing current.

Statement of Problem and Substantiation for Public Comment

First as proposed in PI 1704 in the first draft stage, methods to reduce clearing time should not be required by the NEC for installations where the calculated incident energy at the working distance is 8 cal/cm² or less. Required PPE for this energy level is consistent with the reduced PPE level that will be required after 240.87-approved methods to reduce clearing time are applied to some installations, and consistent with what is needed for some installations that do not fall under 240.87. It is common in many workplaces to provide 8 cal/cm² clothing as daily wear. Second as proposed in PI 1764 in the first draft stage, there should be an exception to these requirements where the breaker serves continuous industrial processes where a lack of protective device coordination will introduce greater or other hazards. All of the measures that could be cost-effectively provided for loads served by an outgoing breaker would introduce some level of protective device miscoordination. Qualified industrial users should be allowed to appropriately manage the full spectrum of hazards, which they could do via the proposed exception.

<tbody>
<tr>
<td>Trough_Bonding.JPG</td>
<td>The pic shows a trough with the panel feed, control wiring and an Ethernet communications cable to support a valve control panel. The several conduits would not physically fit in the panel. The trough intercepted the associated conduits and condensed them to (3) sealights going to the control panel. The completed installation had the communication wiring was separated by 2&quot; from power &amp; control wiring. The communication conduit did not have a ground wire as required by 514.8 ex 2 last sentence. The grounding and bonding was achieved by other approved means. This proposed amendment to 514.8 ex 2 would clarify that it is acceptable to ground and bond by other means.</td>
<td></td>
</tr>
</tbody>
</table>

Statement of Problem and Substantiation for Public Comment

In underground situations where rigid steel conduit transitions to PVC underground and emerges as rigid conduit on both ends. A ground wire is included to bond both ends of the raceway. When there are several conduits in the same enclosure and all are Rigid steel / PVC and some are for communications, the conduit can be bonded to ground without running a ground wire in the conduit with communication cables. If a ground wire was run in with communication cables, the ground fault currents of other circuits could be imposed on the communication cables and damage equipment. The exception to 250.6 (C) would enable the grounding conductor to be removed from the communication conduit. A note should be added that it comply with 250.6 (A) & (B) This would also go along with a proposed change for 514.8 exception 2 to eliminate the requirement of a grounding conductor if it was for a communication cable and the conduit could be bonded by other approved means.

Statement of Problem and Substantiation for Public Comment

Submitted by:
Dan Tharp
Owner and Master Electrician of Big "D" Electric
PO Box 414
Longville, MN. 56655

As a Master electrician for over 30 years, I have witnessed and dealt with the effects of poor grounding. A large part of this stems from the connection point of the GEC to the Grounding Electrode. Section 110.14 of the NEC Handbook describes this issue, yet does not address it completely. Dissimilar metal connections are used frequently in the electrical industry. copper to galvanized ground rods, copper to steel rebar, aluminum to copper ground rods.

Even with "listed" connectors the industry does not address the facts that to dissimilar metals create a battery of such to sacrifices the anode to the cathode. (see attached article)

This is creating a loose and unstable connection point that can lead to a great hazard to both life and property.

The industry also has been led to believe by the creators of exothermic welding that their connections are 100% free from galvanic corrosion. This is proving not to be the case, thus companies such as Century Link, civil engineering firms in St. Louis, Mo and US Dept. of the Interior – Mining and others are requiring a sealant over their exothermic welding connections which are then either buried deep beneath the soil or in concrete. Many companies such as Enbridge and Monsanto require annual inspections of these connections to check that the connection is still sound.

Since the grounding system is dormant a large part of it’s life we as electricians tend to over look it till it’s too late. Once the grounding
system is needed do to a fault or lightning strike occurs we want to have the peace of mind knowing our grounding system is working properly.

Studies show that nearly 86% of all electrical problems stem from poor grounding. While proper installation of grounding equipment is closely regulated, post installation inspection has been largely overlooked. Recent growth spurts in the electrical industry have been bringing attention to these issues, with safety being the utmost concern.

All electrical systems rely on a good ground connection to ensure safe and reliable operation. Making sure there is minimal resistance at the grounding point ensures that any potential hazards are avoided.

The safest and simplest way to achieve these goals are by encapsulating the connection point. As read in the attached paper “Galvanic Corrosion in the Electrical Industry” put together by John Langholtz EE/PE graduate of South Dakota State University.

**Submitter Full Name:** CC on NEC-AAC  
**Organization:** NFPA

**Committee Statement**

**Committee Action:** Rejected but see related SR  
**Resolution:** SR-1203-NFPA 70-2015  
**Statement:** The text is revised to correct transcription errors in the First Revision and to reflect the panel action in the First Revision meeting.
(1) General.

The grounding electrode conductor connection shall be made at any accessible point from the load end of the overhead service conductors, service drop, underground service conductors, or service lateral to, including the terminal or bus to which the grounded service conductor is connected at the service disconnecting means. For the purpose of this section, connection of the grounding electrode conductor in an enclosure that will be sealed or locked by the utility provider shall not be considered accessible, unless such connection is required by the utility provider.

Informational Note: See definitions of Service Conductors, Overhead; Service Conductors, Underground; Service Drop; and Service Lateral in Article 100.

Statement of Problem and Substantiation for Public Comment

If the grounding electrode conductor terminates inside a meterbase, C. T. enclosure, service gutter or similar enclosure that is sealed by the utility company, it is no longer accessible for inspection and maintenance by the electrical inspector or electrical professional. This seal or lock prevents the inspector or electrical personnel from close approach to verify this connection when a modification or repair is done to service equipment. The utility companies seal and sometimes lock all enclosures containing access to conductors on the line side of the metering equipment to prevent tampering and theft of electricity. Over the last 50 years as electricity has become more costly, the problem of theft of service has been an increasing concern to the utility companies.

As inspectors, we are not authorized to break a utility company seal and may have to wait days in order to schedule a utility person to meet on site to remove and re-seal the enclosures, just to insure the grounding electrode connection. This creates a hardship and waists valuable time for the inspector, the utility provider and the electrical personnel who need to get approval from the AHJ to energize the equipment. A connection inside a sealed enclosure is no longer accessible as defined in Article 100. Additional language has been added to the original proposal to exempt this requirement where the connection inside the metering enclosure is required by the utility provider.

Public Input No. 4313-NFPA 70-2014 [Section No. 250.24(A)(1)]

Submitter Information Verification

Submitter Full Name: Rodney Jones
Organization: Clackamas County, Oregon
Affiliation: Self
Street Address:
City:
State:
Zip:
Submittal Date: Fri Sep 04 18:09:25 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The proposed language would limit the ability of the authority having jurisdiction to interpret the NEC to comply with local regulations or practices as provided in 90.4.
Where an ac system operating at 2000 volts or less is grounded at any point, the grounded conductor(s) shall be
routed with the ungrounded conductors to each service disconnecting means and shall be connected to each disconnecting
means grounded conductor(s) terminal or bus. A main bonding jumper shall connect the grounded conductor(s) to each service
disconnecting means enclosure. The grounded conductor(s) shall be installed in accordance with 250.24(C)(1) through
250.24(C)(4).

Exception: Where two or more service disconnecting means are located in a single assembly listed for use as service
equipment, it shall be permitted to connect the grounded conductor(s) to the assembly common grounded conductor(s)
terminal or bus. The assembly shall include a main bonding jumper for connecting the grounded conductor(s) to the assembly
enclosure.

**Statement of Problem and Substantiation for Public Comment**

The voltage level should remain at 1000 volts. Making the change to 2000 volts may allow additional items to comply with low voltage
requirements without substantiation and may create safety issues. Although the change in voltage does not directly impact the
grounding requirements in Article 250, it creates inconsistency with other Articles throughout the code, as other CMP's did not accept
these Public Inputs.

Exception No.2: If a separately derived system is part of mobile system the equipment grounding conductor from the service shall be permitted to be used as the grounding electrode for the separately derived system.

Informational Note No. 1: See 250.104(D) for bonding requirements for interior metal water piping in the area served by separately derived systems.

Informational Note No. 2: See 250.50 and 250.58 for requirements for bonding all electrodes together if located at the same building or structure.

Statement of Problem and Substantiation for Public Comment

In my facility we have numerous test stands that are moved throughout the various labs. These are connected to 480V 3 phase receptacles. On many of the test stands we have a small (generally less than 5 kVA) transformers installed that are used to create 120/240V for a computer, monitor, lab power supply, etc. that are connected to receptacles installed in the bench. To date we have taken a dedicated grounding electrode conductor from the grounded conductor in the derived system to a clamp to building steel to serve as the grounding electrode for the separately derived system.

I have two concerns with this; one due to the portable nature of the test stands it is possible for the dedicated grounding electrode conductor to NOT be connected to building steel as an operator may forget or assume that the equipment grounding conductor in the receptacle does accomplish this and/or the building steel is poorly bonded and does not serve as “good” a grounding electrode as one would hope.

I would like to require only the equipment grounding conductor that supplies the entire receptacle (and therefore the bench) as the grounding electrode to ensure that any time the bench is connected to the 3 phase 480V receptacle the grounded conductors of the separately derived system are connected to a suitable equipment grounding conductor.

Committee Action: Rejected but see related SR
Resolution: SR-1205-NFPA 70-2015
Statement: This revision is an editorial correction to put space between the terms "bus" and "if" in Exception No. 1.
(6) _Grounding Electrode Conductor, Multiple Separately Derived Systems._

A common grounding electrode conductor for multiple separately derived systems shall be permitted. If installed, the common grounding electrode conductor shall be used to connect the grounded conductor of the separately derived systems to the grounding electrode as specified in 250.30(A)(4). A grounding electrode conductor tap shall then be installed from each separately derived system to the common grounding electrode conductor. Each tap conductor shall connect the grounded conductor of the separately derived system to the common grounding electrode conductor. This connection shall be made at the same point on the separately derived system where the system bonding jumper is connected.

Exception No. 1: If the system bonding jumper specified in 250.30(A)(1) is a wire or busbar, it shall be permitted to connect the grounding electrode conductor tap to the equipment grounding terminal, bar, or bus, provided the equipment grounding terminal, bar, or bus is of sufficient size for the separately derived system.

Exception No. 2: A grounding electrode conductor shall not be required for a system that supplies a Class 1, Class 2, or Class 3 circuit and is derived from a transformer rated not more than 1000 volt-amperes, provided the system grounded conductor is bonded to the transformer frame or enclosure by a jumper sized in accordance with 250.30(A)(1). Exception No. 3, and the transformer frame or enclosure is grounded by one of the means specified in 250.134.

(a) Common Grounding Electrode Conductor. The common grounding electrode conductor shall be permitted to be one of the following:

(2) A conductor of the wire type not smaller than 3/0 AWG copper or 250 kcmil aluminum

(3) A metal water pipe that complies with 250.68(C)(2) or is connected to the metal structural frame of the building or structure that complies with 250.68(C)(2) or connected or the metal structural frame of the building or structure that complies with 250.68(C)(2) or connected to the grounding electrode system by a conductor that shall not be smaller than 3/0 AWG copper or 250 kcmil aluminum

(d) Tap Conductor Size. Each tap conductor shall be sized in accordance with 250.66 based on the derived ungrounded conductors of the separately derived system it serves.

Exception: If the source of a separately derived system is located within equipment listed and identified as suitable for use as service equipment, the grounding electrode conductor from the service or feeder equipment to the grounding electrode shall be permitted as the grounding electrode conductor for the separately derived system, if the grounding electrode conductor is of sufficient size for the separately derived system. If the equipment grounding bus internal to the equipment is not smaller than the required grounding electrode conductor for the separately derived system, the grounding electrode connection for the separately derived system shall be permitted to be made to the bus.

(e) Connections. All tap connections to the common grounding electrode conductor shall be made at an accessible location by one of the following methods:

(6) A connector listed as grounding and bonding equipment.

(7) Listed connections to aluminum or copper busbars not smaller than 6 mm thick × 50 mm wide (1/4 in. thick × 2 in. wide) and of sufficient length to accommodate the number of terminations necessary for the installation. If aluminum busbars are used, the installation shall also comply with 250.64(A).

(8) The exothermic welding process.

Tap conductors shall be connected to the common grounding electrode conductor in such a manner that the common grounding electrode conductor remains without a splice or joint.

Statement of Problem and Substantiation for Public Comment

Due to transcription errors in the draft the text is revised to reflect CMP-5 action as reflected in the ballot comment by Charles Mello.

(6) Grounding Electrode Conductor, Multiple Separately Derived Systems.

A common grounding electrode conductor for multiple separately derived systems shall be permitted. If installed, the common grounding electrode conductor shall be used to connect the grounded conductor of the separately derived systems to the grounding electrode as specified in 250.30(A)(4). A grounding electrode conductor tap shall then be installed from each separately derived system to the common grounding electrode conductor. Each tap conductor shall connect the grounded conductor of the separately derived system to the common grounding electrode conductor. This connection shall be made at the same point on the separately derived system where the system bonding jumper is connected.

Exception No. 1: If the system bonding jumper specified in 250.30(A)(1) is a wire or busbar, it shall be permitted to connect the grounding electrode conductor tap to the equipment grounding terminal, bar, or bus, provided the equipment grounding terminal, bar, or bus is of sufficient size for the separately derived system.

Exception No. 2: A grounding electrode conductor shall not be required for a system that supplies a Class 1, Class 2, or Class 3 circuit and is derived from a transformer rated not more than 1000 volt-amperes, provided the system grounded conductor is bonded to the transformer frame or enclosure by a jumper sized in accordance with 250.30(A)(1). Exception No. 3, and the transformer frame or enclosure is grounded by one of the means specified in 250.134.

(a) Common Grounding Electrode Conductor. The common grounding electrode conductor shall be permitted to be one of the following:

(1) A conductor of the wire type not smaller than 3/0 AWG copper or 250 kcmil aluminum

(2) A metal water pipe that complies with 250.68(C)(2) or is connected to the grounding electrode system by a conductor that shall not be smaller than 3/0 AWG copper or 250 kcmil aluminum

(b) Tap Conductor Size. Each tap conductor shall be sized in accordance with 250.66 based on the derived ungrounded conductors of the separately derived system it serves.

Exception: If the source of a separately derived system is located within equipment listed and identified as suitable for use as service equipment, the grounding electrode conductor from the service or feeder equipment to the grounding electrode shall be permitted as the grounding electrode conductor for the separately derived system, if the grounding electrode conductor is of sufficient size for the separately derived system. If the equipment grounding bus internal to the equipment is not smaller than the required grounding electrode conductor for the separately derived system, the grounding electrode connection for the separately derived system shall be permitted to be made to the bus.

(c) Connections. All tap connections to the common grounding electrode conductor shall be made at an accessible location by one of the following methods:

(1) A connector listed as grounding and bonding equipment.

(2) Listed connections to aluminum or copper busbars not smaller than 6 mm × 50 mm (¼ in. × 2 in. wide) and of sufficient length to accommodate the number of terminations necessary for the installation. If aluminum busbars are used, the installation shall comply with 250.64(A).

(3) The exothermic welding process.

Tap conductors shall be connected to the common grounding electrode conductor in such a manner that the common grounding electrode conductor remains without a splice or joint.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs that further consideration be given to the comments expressed in voting on FR 1218.

(6) Grounding Electrode Conductor, Multiple Separately Derived Systems.

A common grounding electrode conductor for multiple separately derived systems shall be permitted. If installed, the common grounding electrode conductor shall be used to connect the grounded conductor of the separately derived systems to the grounding electrode as specified in 250.30(A)(4). A grounding electrode conductor tap shall then be installed from each separately derived system to the common grounding electrode conductor. Each tap conductor shall connect the grounded conductor of the separately derived system to the common grounding electrode conductor. This connection shall be made at the same point on the separately derived system where the system bonding jumper is connected.

Exception No. 1: If the system bonding jumper specified in 250.30(A)(1) is a wire or busbar, it shall be permitted to connect the grounding electrode conductor tap to the equipment grounding terminal, bar, or bus, provided the equipment grounding terminal, bar, or bus is of sufficient size for the separately derived system.

Exception No. 2: A grounding electrode conductor shall not be required for a system that supplies a Class 1, Class 2, or Class 3 circuit and is derived from a transformer rated not more than 1000 volt-amperes, provided the system grounded conductor is bonded to the transformer frame or enclosure by a jumper sized in accordance with 250.30(A)(1), Exception No. 3, and the transformer frame or enclosure is grounded by one of the means specified in 250.134.

(a) Common Grounding Electrode Conductor. The common grounding electrode conductor shall be permitted to be one of the following:

(2) A conductor of the wire type not smaller than 3/0 AWG copper or 250 kcmil aluminum

A metal

(1) The metal frame of the building or structure, or a continuous metal water pipe that complies with 250.68(C)(2) or is connected to the grounding electrode system by a conductor that shall not be smaller than 3/0 AWG copper or 250 kcmil aluminum

(c) Tap Conductor Size. Each tap conductor shall be sized in accordance with 250.66 based on the derived ungrounded conductors of the separately derived system it serves.

Exception: If the source of a separately derived system is located within equipment listed and identified as suitable for use as service equipment, the grounding electrode conductor from the service or feeder equipment to the grounding electrode shall be permitted as the grounding electrode conductor for the separately derived system, if the grounding electrode conductor is of sufficient size for the separately derived system. If the equipment grounding bus internal to the equipment is not smaller than the required grounding electrode conductor for the separately derived system, the grounding electrode connection for the separately derived system shall be permitted to be made to the bus.

(d) Connections. All tap connections to the common grounding electrode conductor shall be made at an accessible location by one of the following methods:

(5) A connector listed as grounding and bonding equipment

(6) Listed connections to aluminum or copper busbars not smaller than 6 mm × 50 mm (1/4 in. × 2 in. wide) and of sufficient length to accommodate the number of terminations necessary for the installation. If aluminum busbars are used, the installation shall comply with 250.64(A).

(7) The exothermic welding process.

Tap conductors shall be connected to the common grounding electrode conductor in such a manner that the common grounding electrode conductor remains without a splice or joint.

Statement of Problem and Substantiation for Public Comment

This is a revision to 250.30 (A) (6) (a) (2) to add back the metal from of the building or structure and to assure the metal water pipe is continuous. As it appears from the Committee Statement that metal frame of the building was not intended to be omitted from this section. In addition, the added words continuous related to the metal water pipe is a requirement that 250.68(C)(2) explains how to accomplish.

Statement: The text is revised to correct transcription errors in the First Revision and to reflect the panel action in the First Revision meeting.

The work “also” was added in 250.30(A)(6)(c)(2) for clarity.

The words “thick” and “wide” were added to the busbar description for consistency.
(6) - Grounding Electrode Conductor, Multiple Separately Derived Systems.

A common grounding electrode conductor for multiple separately derived systems shall be permitted. If installed, the common grounding electrode conductor shall be used to connect the grounded conductor of the separately derived systems to the grounding electrode as specified in 250.30(A)(4). A grounding electrode conductor tap shall then be installed from each separately derived system to the common grounding electrode conductor. Each tap conductor shall connect the grounded conductor of the separately derived system to the common grounding electrode conductor. This connection shall be made at the same point on the separately derived system where the system bonding jumper is connected.

Exception No. 1: If the system bonding jumper specified in 250.30(A)(1) is a wire or busbar, it shall be permitted to connect the grounding electrode conductor tap to the equipment grounding terminal, bar, or bus, provided the equipment grounding terminal, bar, or bus is of sufficient size for the separately derived system.

Exception No. 2: A grounding electrode conductor shall not be required for a system that supplies a Class 1, Class 2, or Class 3 circuit and is derived from a transformer rated not more than 1000 volt-amperes, provided the system grounded conductor is bonded to the transformer frame or enclosure by a jumper sized in accordance with 250.30(A)(1), Exception No. 3, and the transformer frame or enclosure is grounded by one of the means specified in 250.134.

(a) Common Grounding Electrode Conductor. The common grounding electrode conductor shall be permitted to be one of the following:

(2) A conductor of the wire type not smaller than 3/0 AWG copper or 250 kcmil aluminum

(3) A metal water pipe that complies with 250.68(C)(2) or is connected to the grounding electrode system by a conductor that shall not be smaller than 3/0 AWG copper or 250 kcmil aluminum

(d) Tap Conductor Size. Each tap conductor shall be sized in accordance with 250.66 based on the derived ungrounded conductors of the separately derived system it serves.

Exception: If the source of a separately derived system is located within equipment listed and identified as suitable for use as service equipment, the grounding electrode conductor from the service or feeder equipment to the grounding electrode shall be permitted as the grounding electrode conductor for the separately derived system, if the grounding electrode conductor is of sufficient size for the separately derived system. If the equipment grounding bus internal to the equipment is not smaller than the required grounding electrode conductor for the separately derived system, the grounding electrode connection for the separately derived system shall be permitted to be made to the bus.

(e) Connections. All tap connections to the common grounding electrode conductor shall be made at an accessible location by one of the following methods:

(6) A connector listed as grounding and bonding equipment.

(7) Listed connections to aluminum or copper busbars not smaller than 6 mm × 50 mm (\(\frac{1}{4}\) in. × 2 in. wide) and of sufficient length to accommodate the number of terminations necessary for the installation. If aluminum busbars are used, the installation shall comply with 250.64(A).

(8) The exothermic welding process.

Tap conductors shall be connected to the common grounding electrode conductor in such a manner that the common grounding electrode conductor remains without a splice or joint.

Statement of Problem and Substantiation for Public Comment

New rule references 250.68(C)(2), I'm sure this is not the reference the Panel intended, since 68(C)(2) addresses metal structure frame.

(8) The exothermic welding process.

Tap conductors shall be connected to the common grounding electrode conductor in such a manner that the common grounding electrode conductor remains without a splice or joint.

Statement of Problem and Substantiation for Public Comment

250.30(A)(6)(a)(2) proposes to permit the common grounding electrode conductor to be a metal water pipe that complies with 250.68(C)(2). This referenced section [250.68(C)(2)] describes the proper connection of a grounding electrode conductor or bonding jumper to a metal structural frame of a building (not a connection to a metal water pipe). In the 2014 NEC, 250.30(A)(6)(a)(2) did reference the metal frame of a building and compliance to 250.52(A)(2). However, this was proposed to be changed to a metal water pipe with FR 1218. May I suggest that the correct reference in this text be changed to 250.68(C)(1) rather than 250.68(C)(2).
250.68(C)(1) is more appropriate for the proposed text and references connection to a metal water pipe.

Public Comment No. 741-NFPA 70-2015 [ Section No. 250.35(B) ]

(B) Nonseparately Derived System.

1. When a generator is installed as a nonseparately derived system, and overcurrent protection is not integral with the generator assembly, a supply-side bonding jumper shall be installed between the generator equipment grounding terminal and the equipment grounding terminal, bar, or bus of the disconnecting mean(s). It shall be sized in accordance with 250.102(C) based on the size of the conductors supplied by the generator.

2. A non-separately derived generator shall not supply more than one transfer switch (TS) under the following conditions:

   1. One TS supplying a Service disconnect and one TS supplying feeder conductors that are supplied from other service entrance conductors.
   2. Two or more feeders supplied from different sets of service entrance conductors, with a TS supplying each feeder.
   3. Two or more feeders that are each individually supplied from two different separately derived sources, with a TS supplying each feeder.

Statement of Problem and Substantiation for Public Comment

This was originally submitted in 702.10 (PI 2813) However I believe the panel did not understand the parallel path and objective current issues, and assume the performance base directive in 250.6 would be a sufficient deterrent. Please review this issue to see if has merit to be included as a requirement. I have attached four illustrations.

250.35 (B) speaks to when not if

250.35 (B) (2) A non-separately derived generator supplying any downstream feeder panels supplied from different main service disconnects will see the neutral to ground connection (main bonding connection) from the main service disconnect of the other main service disconnect creating a parallel path and a violation of 250.6, even folks that understand section 250.6 do not realize the other service main bonding jumper creates a neutral to ground connection downstream in a feeder panel when supplied from a non-separately derived generator connection. Section 250.24 (A) (5) address the load side of a main service disconnect neutral to bond connection. This is not a load side connection but one from another main service panel. Connecting the generator non-separately derived will create a parallel path and if one of the panels lost a neutral the other service neutral would be overloaded. Another hazard would occur when working on one panels circuit neutrals when a potential from the other panels branch circuit is energized.

This section will NOT preclude more than two main services panels supplied from a common service from being supplied by a non-separately derived generator. This new section will make it clear this type of installation is not permitted.

see Kirchhoff's first Law.

Thank you for this consideration.

<td><strong>Resolution:</strong> The provisions in 250.6 are adequate to address objectionable current.</td>
</tr>
</tbody>
</table>
High-impedance grounded neutral systems in which a grounding impedance, usually a resistor, limits the ground-fault current to a low value shall be permitted for 3-phase ac systems of 480 volts to 2000 volts if all the following conditions are met:

1. The conditions of maintenance and supervision ensure that only qualified persons service the installation.
2. Ground detectors are installed on the system.
3. Line-to-neutral loads are not served.

High-impedance grounded neutral systems shall comply with the provisions of 250.36(A) through (G).

Statement of Problem and Substantiation for Public Comment

The voltage level should remain at 1000 volts. Making the change to 2000 volts may allow additional items to comply with low voltage requirements without substantiation and may create safety issues. Although the change in voltage does not directly impact the grounding requirements in Article 250, it creates inconsistency with other Articles throughout the code, as other CMP's did not accept these Public Inputs.

Committee Statement

Committee Action: Accepted
Resolution: SR-1207-NFPA 70-2015
Statement: The voltage level is reverted to 1000 volts, because voltages above 1000 volts are already covered in 250.187.
(1) Metal Underground Water Pipe.

A. If the power source feeding the building or structure is a dedicated source only to that building or structure, A metal underground water pipe in direct contact with the earth for 3.0 m (10 ft) or more (including any metal well casing bonded to the pipe) and electrically continuous (or made electrically continuous by bonding around insulating joints or insulating pipe) to the points of connection of the grounding electrode conductor and the bonding conductor(s) or jumper(s), if installed.

Statement of Problem and Substantiation for Public Comment

Some neighborhoods have metal water pipes throughout. Many of these homes have transformers feeding more than one home. When more than one structure is served by these transformers and each building bonds their first means of disconnect and then the grounding electrodes utilized are the water pipes, the neutral current imbalance can follow the water pipes into the other structures back to the neutral of the source. This would be a violation of article 250.6. This practice causes objectionable current on the grounding systems and should be only used when the transformers are dedicated for one structure.

Committee Statement
Committee Action: Rejected
Resolution: The submitter’s reference to PI 2173 is misleading. That PI wished to exchange the terms “equipment grounding conductors” for “equipment bonding conductor”. The submitter has not provided documentation of a problem with this commonly provided metal water pipe distribution scheme which includes countless installations for decades.
Public Comment No. 212-NFPA 70-2015 [Section No. 250.52(A)(3)]

(3) Concrete-Encased Electrode.

A concrete-encased electrode shall consist of at least 6.0 m (20 ft) of either (1) or (2):

(1) One or more bare or zinc galvanized or other electrically conductive coated steel reinforcing bars or rods of not less than 13 mm (\(\frac{1}{2}\) in.) in diameter, installed in one continuous 6.0 m (20 ft) length, or if in multiple pieces connected together by the usual steel tie wires, exothermic welding, welding, or other effective means to create a 6.0 m (20 ft) or greater length; or

(2) Bare copper conductor not smaller than 4 AWG

Metallic components shall be encased by at least 50 mm (2 in.) of concrete and shall be located horizontally within that portion of a concrete foundation or footing that is in direct contact with the earth or within vertical foundations or structural components or members that are in direct contact with the earth. If multiple concrete-encased electrodes are present at a building or structure, it shall be permissible to bond only one into the grounding electrode system.

Informational Note 1: Concrete installed with insulation, vapor barriers, films or similar items separating the concrete from the earth is not considered to be in “direct contact” with the earth.

Informational Note 2: Copper, the metal usually used for grounding, is a noble metal and can have serious corrosive effects on underground structures made of iron or steel that are electrically connected to the copper.

Statement of Problem and Substantiation for Public Comment

PI No. 1412 Addressed this proposal and was rejected. I'm proposing it again for reconsideration. The Committee statement is not entirely correct. IEEE 144-2007 does indeed state: “It should be noted that steel rebar, when encased in concrete, has approximately the same potential as copper and thus will not corrode.” This is a true statement only when the steel rebar and the copper are not connected together to form a corrosion cell. If the concrete encased steel rebar is used solely as the grounding electrode and doesn't have an electrical connection to copper, other than through the earth, then it will be perfectly fine. There will be very little to no corrosion.

The problem arises when one connects large amounts of copper to large amounts of concrete encased steel. In these situations, the steel rebar becomes an anode and will sacrifice itself to the copper. Instead of relying on one sentence in IEEE 144 that is seemingly being taken out of context, please consider basic chemical principles and add this note to alert users and inspectors of the potential corrosion problem. Most users and inspection authorities are unaware of this issue since it's not an electrical safety issue. Even though this isn't an electrical safety issue if foundation rebar or structural steel corrodes there could be a structural safety issue.

Submittal Date: Mon Jul 13 13:46:02 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: No new information has been provided on this subject. The Panel statement as provided for Public Input 1412 is applicable. The submitter has not provided documentation indicating that use of concrete-encased steel in accordance with the provisions of section 250.52(A)(3) will cause significant deterioration of the structural reinforcing steel. As stated in the resolve of PI 1412, which references IEEE 144 - 2007 4.4.5, pg. 181, “It should be noted that steel rebar, when encased in concrete, has approximately the same potential as copper and thus will not corrode.”
Other Local Metal Underground Systems or Structures.

Other local metal underground systems or structures such as piping systems, underground tanks, and underground metal well casings that are not bonded to a metal water pipe. The structures and structural reinforcing steel described at 680.26(B)(1) and (B)(2) shall not be considered as a grounding electrode described by this section.
Public Comment No. 1738-NFPA 70-2015 [Section No. 250.52(A)(8)]

(8) Other Local Metal Underground Systems or Structures.

Other local metal underground systems or structures such as piping systems, underground tanks, and underground metal well casings that are not bonded to a metal water pipe. The structures and structural reinforcing steel described at 680.26(B)(1) and (B)(2) shall not be considered as a grounding electrode described by this section.

Statement of Problem and Substantiation for Public Comment

Delete the last sentence added during the first revision. The language in 680.26(B) refers to "remote" panelboards, service equipment or electrodes and does not apply to all situations.

Rod and Pipe Electrodes.

The electrode shall be installed such that at least 2.44 m (8 ft) of length is in contact with the soil. It shall be driven to a depth of not less than 2.44 m (8 ft) except that, where rock bottom is encountered, the electrode shall be driven at an oblique angle not to exceed 45 degrees from the vertical or, where rock bottom is encountered at an angle up to 45 degrees, the electrode shall be permitted to be buried in a trench that is at least 750 mm (30 in.) deep. The upper end of the electrode shall be flush with or below ground level unless the aboveground end and the grounding electrode conductor attachment are protected against physical damage as specified in 250.10.

Additional Proposed Changes

File Name Description Approved
2017_NECChangeProposal.pdf

Statement of Problem and Substantiation for Public Comment

As a Master electrician for over 30 years, I have witnessed and dealt with the effects of poor grounding. A large part of this stems from the connection point of the GEC to the Grounding Electrode. Section 110.14 of the NEC Handbook describes this issue, yet does not address it completely. Dissimilar metal connections are used frequently in the electrical industry. Copper to galvanized ground rods, copper to steel rebar, aluminum to copper ground rods.

Even with "listed" connectors the industry does not address the facts that to dissimilar metals create a battery of such to sacrifices the anode to the cathode.
(see attached article)

This is creating a loose and unstable connection point that can lead to a great hazard to both life and property.

The industry also has been led to believe by the creators of exothermic welding that their connections are 100% free from galvanic corrosion. This is proving not to be the case, thus companies such as Century Link, civil engineering firms in St. Louis, Mo and US Dept. of the Interior – Mining and others are requiring a sealant over their exothermic welding connections which are then either buried deep beneath the soil or in concrete. Many companies such as Enbridge and Monsanto require annual inspections of these connections to check that the connection is still sound.

Since the grounding system is dormant a large part of it's life we as electricians tend to over look it till it's too late. Once the grounding system is needed do to a fault or lightning strike occurs we want to have the peace of mind knowing our grounding system is working properly.

Studies show that nearly 86% of all electrical problems stem from poor grounding. While proper installation of grounding equipment is closely regulated, post installation inspection has been largely overlooked. Recent growth spurt in the electrical industry have been bringing attention to these issues, with safety being the utmost concern.

All electrical systems rely on a good ground connection to ensure safe and reliable operation. Making sure there is minimal resistance at the grounding point ensures that any potential hazards are avoided.

The safest and simplest way to achieve these goals are by encapsulating the connection point. As read in the attached paper “Galvanic Corrosion in the Electrical Industry” put together by John Langholtz EE/PE graduate of South Dakota State University.

**Public Comment No. 1541-NFPA 70-2015 [ Section No. 250.58 ]**

**250.58  Common Grounding Electrode.**

Where an ac system is connected to a grounding electrode in or at a building or structure, the same electrode shall be used to ground conductor enclosures and equipment in or on that building or structure. Where separate services, feeders, or branch circuits supply a building and are required to be connected to a grounding electrode(s), the same grounding electrode(s) shall be used. Where two or more buildings or structures with individual services are present on the same premise and have common electrical or communications systems, the grounding electrodes serving the buildings or structures shall be bonded together.

Two or more grounding electrodes that are bonded together shall be considered as a single grounding electrode system in this sense.

**Statement of Problem and Substantiation for Public Comment**

In PI 1465, the submitter requested that the grounding electrodes of multiple buildings on the same property be bonded together. The panel responded that the submitter did not provide adequate substantiation to require all cases of multiple buildings or structures on one property to have the grounding electrodes of the buildings connected together. In the submitter's example, the separate buildings each had a service, but shared common lighting, fire alarm and communications systems. In this specific case, it would be prudent to bond the grounding electrodes together.

**Committee Statement**

Committee Action: Rejected

Resolution: Adding this as a requirement could create a path for objectionable current. Adequate substantiation has not been provided to require all buildings and structures to have their grounding electrode systems connected together. The buildings or structures described in the proposed language could be a considerable distance apart.
Public Comment No. 1772-NFPA 70-2015 [Section No. 250.60]

250.60 Use of Strike Termination Devices.
Conductors and driven pipes, rods, or plate electrodes used for grounding strike termination devices shall not be used in lieu of the grounding electrodes required by 250.50 for grounding wiring systems and equipment. This provision shall not prohibit the required bonding together of grounding electrodes of different systems.

Informational Note No. 1: See 250.106 for spacing from lightning protection system components. See 800.100(D), 810.21(J), and 820.100(D) for bonding of electrodes.

Informational Note No. 2: Bonding together of all separate grounding electrodes will limit voltage differences between them and between their associated wiring systems.

Statement of Problem and Substantiation for Public Comment
The Correlating Committee directs that further consideration be given to the comments expressed in voting on FR 7510.

Committee Statement
Committee Action: Rejected
Resolution: Panel 5 has reviewed the voting comments to FR 7510 and has determined that they are not applicable.
250.60 Use of Strike Termination Devices.

Conductors and driven pipes, rods, or plate electrodes used for grounding strike termination devices shall not be used in lieu of the grounding electrodes required by 250.50 for grounding wiring systems and equipment. This provision shall not prohibit the required bonding together of grounding electrodes of different systems.

Informational Note No. 1: See 250.106 for spacing from the bonding requirement of the lightning protection system components. See 800.100(D) - 810.21(J) and 820.100(D) for bonding of electrodes, electrode to the building or structure grounding electrode system.

Informational Note No. 2: Bonding together of all separate grounding electrodes will limit voltage differences between them and between their associated wiring systems.

Statement of Problem and Substantiation for Public Comment

Note No. 1 was always wrong, 250.106 has nothing to do with spacing of lighting protection systems, it has to do with bonding of LPS electrode to the building/structure electrode. Also deleting the references to Chapter 8 rules removes references that have nothing to do the LPS electrodes, that is covered in 250.106.

Statement of Problem and Substantiation for Public Comment

There is no reason to approve the change to the language of the 2014 NEC. The device is not listed for exterior exposure and would present a safety issue if corrosion of an aluminum conductor occurred, as is likely within 18 inches of the earth. The term "suitable" is not a recognized term and is not defined.

Committee Statement

Committee Action: Rejected
Resolution: The proposed last sentence is unclear, unenforceable, and does not contain mandatory language.
Public Comment No. 789-NFPA 70-2015 [Section No. 250.64(A)]

(A) Aluminum or Copper-Clad Aluminum Conductors.

Bare aluminum or copper-clad aluminum grounding electrode conductors shall not be used where in direct contact with masonry or the earth. Where installed outside of a building or enclosure, aluminum or copper-clad aluminum grounding electrode conductors shall not be terminated within 450 mm (18 in.) of the earth, unless the termination method is listed as a sealed wire-connector system. Terminations made within listed enclosures suitable for outdoor use shall be permitted within 450 mm (18 in.) of the earth.

Statement of Problem and Substantiation for Public Comment

Listed sealed wire-connector systems have not been evaluated for sealing of bare or uninsulated conductors. The following information is from the UL White Book in ZMWQ:

This category covers sealed wire-connector systems intended for wet or damp locations and other installations, such as direct burial, below grade, or above grade where protected from direct exposure to sunlight. These systems may also be used indoors or in dry locations.

Sealed wire-connector systems are intended for use in installations covered by ANSI/NFPA 70, "National Electrical Code."

Sealed wire-connector systems have not been investigated for direct exposure to sunlight. Additional performance considerations to show equivalency to the connected conductors should be considered for UV exposure.

Sealed wire-connector systems have not been investigated for direct exposure to salt or seawater.

This category covers a complete system or insulating caps, covers, resins, tubing and tapes that are part of the system for use with specific wire connectors where the seal is made at the conductor. Pressure wire connectors may or may not be provided with the system.

In addition, the phrase in the last sentence relative to the use of the term "suitable" is inappropriate and not defined in the NEC. This substantiates the deletion of the last sentence.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-1212-NFPA 70-2015
Statement: This subdivision was revised into a list format to improve usability. The word "covered" was added to be consistent with other sections of the NEC. The phrase "or where subject to corrosive conditions" was added to list item 1 to correct a transcription error. List item 3 was revised to replace "suitable" with "identified" as it is a defined term. The phrase "listed as grounding and bonding equipment" was added to ensure the connectors are evaluated for fault current and to allow a product to be made available.
Public Comment No. 1592-NFPA 70-2015 [Section No. 250.64(B)]

| (B) | Securing and Protection Against Physical Damage.  
Where exposed, a grounding electrode conductor or its enclosure shall be securely fastened to the surface on which it is carried. Grounding electrode conductors shall be permitted to be installed on or through framing members. 300.5. |
|---|---|
| (1) | Not Exposed to Physical Damage.  
A 6 AWG or larger copper or aluminum grounding electrode conductor not exposed to physical damage shall be permitted to be run along the surface of the building construction without metal covering or protection. |
| (2) | Exposed to Physical Damage.  
A 6 AWG or larger copper or aluminum grounding electrode conductor exposed to physical damage shall be protected in rigid metal conduit (RMC), intermediate metal conduit (IMC), rigid polyvinyl chloride conduit (PVC) XW-type, reinforced thermosetting resin conduit (RTRC-XW), electrical metallic tubing (EMT), or cable armor. |
| (3) | Smaller Than 6 AWG.  
Grounding electrode conductors smaller than 6 AWG shall be protected in RMC, IMC, PVC XW-type, RTRC-XW, EMT, or cable armor. |
| (4) | In Contact with the Earth.  
Grounding electrode conductors and grounding electrode bonding jumpers in contact with the earth shall not be required to comply with 300.5, but shall be buried or otherwise protected if subject to physical damage. |

Statement of Problem and Substantiation for Public Comment

Due to transcription errors the Draft test was not reflected from the Panel actions. See ballot comment from Charles Mello. In list item 3, the "XW-type" was added to be consistent with the requirements in list item 2.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-1214-NFPA 70-2015
Statement: The words "an electrically" were added to be consistent with how that phrase is typically used to improve clarity.
250.66 Size of Alternating-Current Grounding Electrode Conductor.

The size of the grounding electrode conductor at the service, at each building or structure where supplied by a feeder(s) or branch circuit(s), or at a separately derived system of a grounded or ungrounded ac system shall not be less than given in Table 250.66, except as permitted in 250.66(A) through (C).

Notes:
1. If multiple sets of service-entrance conductors connect directly to a service drop, set of overhead service conductors, set of underground service conductors, or service lateral, the equivalent size of the largest service-entrance conductor shall be determined by the largest sum of the areas of the corresponding conductors of each set.
2. Where there are no service-entrance conductors, the grounding electrode conductor size shall be determined by the equivalent size of the largest service-entrance conductor required for the load to be served.

aThis table also applies to the derived conductors of separately derived ac systems.

bSee installation restrictions in 250.64(A).

(A) Connections to a Rod, Pipe, or Plate Electrode(s).

Where the grounding electrode conductor or bonding jumper connected to a single or multiple rod, pipe, or plate electrode(s), or any combination thereof, as permitted in 250.52(A)(5) or (A)(7), does not extend on to other types of electrodes, the grounding electrode conductor shall not be required to be larger than 6 AWG copper wire or 4 AWG aluminum wire.

(B) Connections to Concrete-Encased Electrodes.

Where the grounding electrode conductor or bonding jumper connected to a single or multiple concrete-encased electrode(s), as permitted in 250.52(A)(3), does not extend on to other types of electrodes that require a larger size conductor, the grounding electrode conductor shall not be required to be larger than 4 AWG copper wire.

(C) Connections to Ground Rings.

Where the grounding electrode conductor or bonding jumper connected to a ground ring, as permitted in 250.52(A)(4), does not extend on to other types of electrodes that require a larger size conductor, the grounding electrode conductor shall not be required to be larger than the conductor used for the ground ring.

Statement of Problem and Substantiation for Public Comment

Due to transcription errors the Draft text did not reflect the panel action. See ballot comments of Charles Mello.

Public Comment No. 489-NFPA 70-2015 [Sections 250.66(A), 250.66(B), 250.66(C)]

Sections 250.66(A), 250.66(B), 250.66(C)

(A) Connections to a Rod, Pipe, or Plate Electrode(s).
Where if the grounding electrode conductor connected to a single or multiple rod, pipe, or plate electrode(s) — or any combination thereof — as permitted in 250.52(A)(5) or (A)(7) — does not extend on to other types of electrodes that require a larger size of conductor then the grounding electrode conductor shall not be required to be larger than 6 AWG copper wire or 4 AWG aluminum wire.

(B) Connections to Concrete-Encased Electrodes.
Where if the grounding electrode conductor connected to a single or multiple concrete-encased electrode(s) — as permitted in 250.52(A)(3) — does not extend on to other types of electrodes that require a larger size of conductor then the grounding electrode conductor shall not be required to be larger than 4 AWG copper wire.

(C) Connections to Ground Rings.
Where if the grounding electrode conductor connected to a ground ring — as permitted in 250.52(A)(4) — does not extend on to other types of electrodes that require a larger size of conductor then the grounding electrode conductor shall not be required to be larger than the conductor used for the ground ring.

Statement of Problem and Substantiation for Public Comment

The term "that require a larger size of conductor" was included in B and C but not A. There is no indication in the proposal or the CMP statement that would lead to the conclusion that this term was not supposed to be in all 3 sections and was just inadvertently left off of A.

Removed a number of commas and changed "Where" to "If" to make the sentences a little more readable.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-1215-NFPA 70-2015
Statement: The phrase "or bonding jumper" was added to each subdivision to correct a transcription error in the first draft. The phrase "that require a larger size conductor" was added to (A) to be consistent with the other subdivisions. The term "permitted" was changed to "described" for accuracy.
(C) Grounding Electrode Connections.

Grounding electrode conductors and bonding jumpers shall be permitted to be connected at the following locations and used to extend the connection to an electrode(s):

1. Interior Connection to interior metal water piping shall be located not more than 1.52 m (5 ft) from the point of entrance to the building.
   
   Exception: In industrial, commercial, and institutional buildings or structures, if conditions of maintenance and supervision ensure that only qualified persons service the installation, interior metal water piping located more than 1.52 m (5 ft) from the point of entrance to the building shall be permitted as a bonding conductor to interconnect electrodes that are part of the grounding electrode system, or as a grounding electrode conductor, if the entire length, other than short sections passing perpendicularly through walls, floors, or ceilings, of the interior metal water pipe that is being used for the conductor is exposed.

2. The metal structural frame of a building shall be permitted to be used as a conductor to interconnect electrodes that are part of the grounding electrode system, or as a grounding electrode conductor. Hold-down bolts securing the structural steel column that are connected to a concrete-encased electrode that complies with 250.52(A)(3) and is located in the support footing or foundation shall be permitted to connect the metal structural frame of a building or structure to the concrete encased grounding electrode. The hold-down bolts shall be connected to the concrete-encased electrode by welding, exothermic welding, the usual steel tie wires, or other approved means.

3. A rebar type concrete-encased electrode installed in accordance with 250.52(A)(3) with an additional rebar section extended from its location within the concrete to an accessible location that is not subject to corrosion shall be permitted for connection of the grounding electrode conductor. The rebar extension shall not be exposed to contact with the earth without corrosion protection.

Statement of Problem and Substantiation for Public Comment

Edited text in the Draft was not from the committee action and result was incorrect requirement. Revised text provided to meet editorial requirements and clarify this item.

Submittal Date: Fri Sep 25 15:12:41 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-1216-NFPA 70-2015
Statement:

The word "conductor" was added to the title of 250.68(C) to more accurately reflect the application of the section.

The phrase "that is continuous with a metal underground water pipe electrode and is" was added to 250.68(C)(1) to be clear that the interior water piping connection is only permitted if the piping is continuous to the underground portion.

The phrase "shall be" was deleted to correct a transcription error in the first draft.

The second sentence of 250.68(C)(1) was added to provide clear language to not allow water piping beyond 5 ft from being used as a connection point unless the exception applies.

The term "bonding jumpers" was added to 250.68(C)(3) to be consistent with the title of 250.68.
(C) Grounding Electrode Connections.

Grounding electrode conductors and bonding jumpers shall be permitted to be connected at the following locations and used to extend the connection to an electrode(s):

(1) Interior metal water piping shall be located not more than 1.52 m (5 ft) from the point of entrance to the building. 

*Exception: In industrial, commercial, and institutional buildings or structures, if conditions of maintenance and supervision ensure that only qualified persons service the installation, interior metal water piping located more than 1.52 m (5 ft) from the point of entrance to the building shall be permitted as a bonding conductor to interconnect electrodes that are part of the grounding electrode system, or as a grounding electrode conductor, if the entire length, other than short sections passing perpendicularly through walls, floors, or ceilings, of the interior metal water pipe that is being used for the conductor is exposed.*

(2) The metal structural frame of a building shall be permitted to be used as a conductor to interconnect electrodes that are part of the grounding electrode system, or as a grounding electrode conductor. Hold-down bolts securing the structural steel column that are connected to a concrete-encased electrode that complies with 250.52(A)(3) and is located in the support footing or foundation shall be permitted to connect the metal structural frame of a building or structure to the concrete encased grounding electrode. The hold-down bolts shall be connected to the concrete-encased electrode by welding, exothermic welding, the usual steel tie wires, or other approved means.

(3) A rebar type concrete-encased electrode installed in accordance with 250.52(A)(3) with an additional rebar section extended from its location within the concrete to an accessible location that is not subject to corrosion shall be permitted for connection of the grounding electrode conductor. The rebar extension shall not be exposed to contact with the earth without corrosion protection.

**Statement of Problem and Substantiation for Public Comment**

The Correlating Committee directs that further consideration be given to the comments expressed in voting on FR 1228.

Public Comment No. 301-NFPA 70-2015 [Section No. 250.68(C)]

(C) Other Than Grounding Electrode Connections.

Grounding electrode conductors and bonding jumpers shall be permitted to be connected at the following locations and used to extend the connection to an electrode(s):

1. Interior metal water piping shall be continuous with a metal underground water pipe electrode, located not more than 1.52 m (5 ft) from the point of entrance to the building.

   *Exception:* In industrial, commercial, and institutional buildings or structures, if conditions of maintenance and supervision ensure that only qualified persons service the installation, interior metal water piping located more than 1.52 m (5 ft) from the point of entrance to the building shall be permitted as a bonding conductor to interconnect electrodes that are part of the grounding electrode system, or as a grounding electrode conductor, if the entire length, other than short sections passing perpendicularly through walls, floors, or ceilings, of the interior metal water pipe that is being used for the conductor is exposed.

2. The metal structural frame of a building shall be permitted to be used as a conductor to interconnect electrodes that are part of the grounding electrode system, or as a grounding electrode conductor. Hold-down bolts securing the structural steel column that are connected to a concrete-encased electrode that complies with 250.52(A)(3) and is located in the support footing or foundation shall be permitted to connect the metal structural frame of a building or structure to the concrete encased grounding electrode. The hold-down bolts shall be connected to the concrete-encased electrode by welding, exothermic welding, the usual steel tie wires, or other approved means.

3. A rebar type concrete-encased electrode installed in accordance with 250.52(A)(3) with an additional rebar section extended from its location within the concrete to an accessible location that is not subject to corrosion shall be permitted for connection of the grounding electrode conductor and bonding jumpers. The rebar extension shall not be exposed to contact with the earth without corrosion protection.

Statement of Problem and Substantiation for Public Comment

The title modification clarifies these connections are "other than" direct to a grounding electrode as permitted under 250.64(F).

Revised text in (1) clarifies the interior metal water piping must be continuous with a qualifying metal underground water pipe electrode.

Revised text in (3) allows connection of bonding jumpers to this location.

Changed "extention" to the proper spelling: "extension".

The rebar extension shall not be exposed to contact with the earth without corrosion protection.

Statement of Problem and Substantiation for Public Comment

The language in this PI was not adapted correctly from the submitted original proposal in the PI first draft. The current language as shown is confusing and inaccurate. Corrections have been made to clarify the language and the original intent of the submitter. In general, the first 5-feet of a utility water pipe allowed for use as a grounding electrode in 250.52(A)(1), measured from the point where the pipe enters the building, has in previous editions of the code been permitted to be used as a grounding electrode and interconnection point for grounding electrode conductors. Metal piping beyond 5-feet from the entrance to the building must be bonded in compliance with 250.104 but is not allowed to be used as a grounding electrode or an interconnecting point for a grounding electrode conductor. The language currently shown in 250.68(C)(1) (2014 edition) provides permissive language and suggests code users can use metal piping further than 5-feet as a grounding electrode and/or interconnection point for grounding electrode conductors. Proper language of this section needs revision to provide clarity for code users and to ensure proper installation techniques for safe installations. The danger of allowing metal piping further than 5-feet from the point of entry into a building as a grounding electrode or an interconnection point for grounding electrode conductors may be present if sections of the metal water pipe are removed and replace with plastic piping products, thus eliminating the metallic pathway to the earth ground.

250.80  Service Raceways and Enclosures.

Metal enclosures and raceways for service conductors and equipment shall be connected to the grounded system conductor if the electrical system is grounded or to the grounding electrode conductor for electrical systems that are not grounded.

Exception: Metal components that are installed in a run of underground nonmetallic raceway(s) and are isolated from possible contact by a minimum cover of 450 mm (18 in.) to all parts of the metal components shall not be required to be connected to the grounded system conductor, supply side bonding jumper, or grounding electrode conductor.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs that further consideration be given to the comments expressed in voting on FR 1206.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-1217-NFPA 70-2015
Statement: The phrase "metal components" was added to each subdivision to correct a transcription error in the first draft. Isolated sections of metal conduit that meet the requirements of this section are considered to be metal components.

The exception was converted to a list to improve usability.
250.86  Other Conductor Enclosures and Raceways.
Except as permitted by 250.112(I), metal enclosures and raceways for other than service conductors shall be connected to the equipment grounding conductor.

Exception No. 1: Metal enclosures and raceways for conductors added to existing installations of open wire, knob-and-tube wiring, and nonmetallic-sheathed cable shall not be required to be connected to the equipment grounding conductor where these enclosures or wiring methods comply with (1) through (4) as follows:

(1) Do not provide an equipment ground
(2) Are in runs of less than 7.5 m (25 ft)
(3) Are free from probable contact with ground, grounded metal, metal lath, or other conductive material
(4) Are guarded against contact by persons

Exception No. 2: Short sections of metal enclosures or raceways used to provide support or protection of cable assemblies from physical damage shall not be required to be connected to the equipment grounding conductor.

Exception No. 3: A metal elbow. Metal components shall not be required to be connected to the equipment grounding conductor or supply side bonding jumper where it is installed in a run of nonmetallic raceway and is (s) and are isolated from possible contact by a minimum cover of 450 mm (18 in.) to any part of the elbow or is, metal components or are, encased in not less than 50 mm (2 in.) of concrete.

Statement of Problem and Substantiation for Public Comment

Due to transcription errors the panel change in this section to mirror the same changes in 250.80 were missed. See ballot comments from Charles Mello

3. Are free from probable contact with ground, grounded metal, metal lath, or other conductive material
4. Are guarded against contact by persons

Exception No. 2: Short sections of metal enclosures or raceways used to provide support or protection of cable assemblies from physical damage shall not be required to be connected to the equipment grounding conductor.

Exception No. 3: A metal elbow or sections of metal conduit shall not be required to be connected to the equipment grounding conductor where it is installed in a run of nonmetallic raceway and is isolated from possible contact by a minimum cover of 450 mm (18 in.) to any part of the elbow or conduit or is encased in not less than 50 mm (2 in.) of concrete.

Statement of Problem and Substantiation for Public Comment

I have seen requirements in contract notes on more than one occasion to provide Rigid Metal Conduit (under driveways only) along a street lighting PVC run spanning a block or more. Although I believe that PVC buried more than 18" (in this case 24") would not be a physical protection issue under a driveway, the engineer is requiring short sections of RMC under each driveway. Section 250.86 Exception #3 states "elbows" are not required to be grounded. I would like to see this exception include "short sections of RMC conduit" added. As grounding these sections causes unnecessary additional costs and effective grounding issues.

Committee Action: Rejected but see related SR
Resolution: SR-1217-NFPA 70-2015
Statement: The phrase "metal components" was added to each subdivision to correct a transcription error in the first draft. Isolated sections of metal conduit that meet the requirements of this section are considered to be metal components.

The exception was converted to a list to improve usability.
Public Comment No. 704-NFPA 70-2015 [ Section No. 250.94 ]

**250.94. Bonding for Non-Communication Systems.**

**Communications system bonding.** For non-communications systems (such as gas piping), the bonding terminations shall be connected in accordance with (A) or (B).

(A). The Intersystem Bonding Termination Device.

The following:

An intersystem bonding termination (IBT) for connecting intersystem bonding conductors shall be provided external to enclosures at the service equipment or metering equipment enclosure and at the disconnecting means for any additional buildings or structures. If an IBT is used, it shall comply with the following:

1. Be accessible for connection and inspection.
2. Consist of a set of terminals with the capacity for connection of not less than three intersystem bonding conductors.
3. Not interfere with opening the enclosure for a service, building or structure disconnecting means, or metering equipment.
4. At the service equipment, be securely mounted and electrically connected to an enclosure for the service equipment, to the meter enclosure, or to an exposed nonflexible metallic service raceway, or be mounted at one of these enclosures and be connected to the enclosure or to the grounding electrode conductor with a minimum 6 AWG copper conductor.
5. At the disconnecting means for a building or structure, be securely mounted and electrically connected to the metallic enclosure for the building or structure disconnecting means, or be mounted at the disconnecting means and be connected to the metallic enclosure or to the grounding electrode conductor with a minimum 6 AWG copper conductor.
6. The terminals shall be listed as grounding and bonding equipment.

**Exception:** In existing buildings or structures where any of the intersystem bonding and grounding electrode conductors required by 770.100(B)(2), 800.100(B)(2), 810.21(F)(2), 820.100(B)(2), and 830.100(B)(2) exist, installation of the intersystem bonding termination is not required. An accessible means external to enclosures for connecting intersystem bonding and grounding electrode conductors shall be permitted at the service equipment and at the disconnecting means for any additional buildings or structures by at least one of the following means:

1. Exposed nonflexible metallic raceways
2. An exposed grounding electrode conductor
3. Approved means for the external connection of a copper or other corrosion-resistant bonding or grounding electrode conductor to the grounded raceway or equipment

**Informational Note No. 1:** A 6 AWG copper conductor with one end bonded to the grounded nonflexible metallic raceway or equipment and with 150 mm (6 in.) or more of the other end made accessible on the outside wall is an example of the approved means covered in **250.94.** Exception item (3).

**Informational Note No. 2:** See 770.100, 800.100, 810.21, 820.100, and 830.100 for intersystem bonding and grounding requirements for conductive optical fiber cables, communications circuits, radio and television equipment, CATV circuits and network-powered broadband communications systems, respectively.

(B). Other Means.

Connections to an aluminum or copper busbar not less than 6 mm thick × 50 mm wide (% in. thick × 2 in. wide) and of sufficient length to accommodate at least three terminations for communication systems in addition to other connections. The busbar shall be securely fastened and shall be installed in an accessible location. Connections shall be made by a listed connector. If aluminum busbars are used, the installation shall also comply with **250.64(A).**

**Exception to (A) and (B):** Means for connecting intersystem bonding conductors are not required where communications systems are not likely to be used.

**Informational Note:** The use of an IBT can reduce electrical noise on communication systems.

Statement of Problem and Substantiation for Public Comment

Substantiation: The rejection of the original PI (3837 and 3838) by CMP-5 was based on the revised definition and limitation of the Intersystem Bonding Termination (IBT) to communication systems only. However, the 2011 NEC acknowledged the possibility of additional bonding requirements for gas piping in an Informational Note located in Section 250.104(B). With the change in 2009 NFPA 54 Code requiring the additional bonding of CSST gas piping systems to the grounding electrode system, an IBT for non-communication systems provides a viable and appropriate connection for this purpose. Over six million existing homes have CSST installed without this additional bonding conductor. The National Association of State Fire Marshals has been actively promoting a public safety campaign within the NFPA community to encourage retroactive installation of the CSST bonding conductor. In some states, the bonding of CSST systems can be performed by someone other than a licensed electrician. The allowance for this bonding conductor to be installed at an IBT will aid in keeping unqualified persons out of potentially hazardous situations inside an energized panel board.
while attempting to terminate the CSST gas piping bonding conductor. The requirement for extra bonding of CSST systems has been reconfirmed by the NFPA 54 Technical Committee in both the 2012 and 2015 editions. Allowing an additional IBT will not interfere with the functioning of the communications only IBT, and will it improve electrical safety for the gas piping system.

Committee Statement

Committee Action: Rejected
Resolution: There are no changes needed, based on the ballot comments.
(A) The Intersystem Bonding Termination Device.

An intersystem bonding termination (IBT) for connecting intersystem bonding conductors shall be provided external to enclosures at the service equipment or metering equipment enclosure and at the disconnecting means for any additional buildings or structures. If an IBT is used, it shall comply with the following:

1. Be accessible for connection and inspection.
2. Consist of a set of terminals with the capacity for connection of not less than three intersystem bonding conductors.
3. Not interfere with opening the enclosure for a service, building or structure disconnecting means, or metering equipment.
4. At the service equipment, be securely mounted and electrically connected to an enclosure for the service equipment, to the meter enclosure, or to an exposed nonflexible metallic service raceway, or be mounted at one of these enclosures and be connected to the enclosure or to the grounding electrode conductor with a minimum 6 AWG copper conductor.
5. At the disconnecting means for a building or structure, be securely mounted and electrically connected to the metallic enclosure for the building or structure disconnecting means, or be mounted at the disconnecting means and be connected to the metallic enclosure or to the grounding electrode conductor with a minimum 6 AWG copper conductor.
6. The terminals shall be listed as grounding and bonding equipment, and listed for the environment in which they are installed.

Exception: In existing buildings or structures where any of the intersystem bonding and grounding electrode conductors required by 770.100(B)(2), 800.100(B)(2), 810.21(F)(2), 820.100(B)(2), and 830.100(B)(2) exist, installation of the intersystem bonding termination is not required. An accessible means external to enclosures for connecting intersystem bonding and grounding electrode conductors shall be permitted at the service equipment and at the disconnecting means for any additional buildings or structures by at least one of the following means:

1. Exposed nonflexible metallic raceways
2. An exposed grounding electrode conductor
3. Approved means for the external connection of a copper or other corrosion-resistant bonding or grounding electrode conductor to the grounded raceway or equipment

Informational Note No. 1: A 6 AWG copper conductor with one end bonded to the grounded nonflexible metallic raceway or equipment and with 150 mm (6 in.) or more of the other end made accessible on the outside wall is an example of the approved means covered in 250.94, Exception item (3).

Informational Note No. 2: See 770.100, 800.100, 810.21, 820.100, and 830.100 for intersystem bonding and grounding requirements for conductive optical fiber cables, communications circuits, radio and television equipment, CATV circuits and network-powered broadband communications systems, respectively.

Statement of Problem and Substantiation for Public Comment

Since the Code Panel made reference to an Exception, there must be confusion as to what this change would be. Googling these intersystem bonding terminals on the internet one can see just how many are offered. The concern is finding one listed but not for a wet location and having questionable terminals as to that environment. It would seem only a reminder for the wet location listing or identifying, where the entire Code provides for that in many areas already. Is the Code Making Panel suggesting there is no need for this testing as a part of the listing?

And what Exception would this interfere with?

Public Comment No. 368-NFPA 70-2015 [Section No. 250.94(B)]

(B) Other Means.

Connections to an aluminum or copper busbar not less than 6 mm thick × 50 mm wide (¼ in. thick × 2 in. wide) and of sufficient length to accommodate at least three terminations for communication systems in addition to other connections. The busbar shall be securely fastened and shall be installed in an accessible location. Connections shall be made by a listed connector. If aluminum busbars are used, the installation shall also comply with 250.64(A).

Exception to (A) and (B): Means for connecting intersystem bonding conductors are not required where communications systems are not likely to be used.

Informational Note: The use of an IBT can reduce electrical noise on communication systems.

Statement of Problem and Substantiation for Public Comment

I'm sure none of the Panel 5 members could actually draw out a circuit to demonstrate how an ITBT could reduce noise on communications' systems. In addition, I'm sure if the Panel actually took some time, they would not be able to come up with the definition of electrical noise. As a matter of fact, the ITBT would actually add to the issue of 'noise' if there were multiple neutral-to-ground connections in a premises. How about we just not add information to the NEC that is not true or a fact.

Resolution: SR-1219-NFPA 70-2015
Statement: Further consideration was given to the comments expressed in voting on FR 7509 in accordance with the direction of the Correlating Committee. It was determined that the intended revisions to Table 250.102(C)(1) were not shown in FR 7509. In addition, the second informational note in 250.102(C)(2) was incorrectly relocated in FR 7509. The proposed second revision corrects these transcription errors.
Public Comment No. 1634-NFPA 70-2015 [Section No. 250.102(C)(2)]

(2) Size for Parallel Conductor Installations in Two or More Raceways or Cables.

Where the ungrounded supply conductors are paralleled in two or more raceways or cables, and an individual supply-side bonding jumper is used for bonding these raceways or cables, the size of the supply-side bonding jumper for each raceway or cable shall be selected from Table 250.102(C)(1) based on the size of the ungrounded supply conductors in each raceway or cable. A single supply-side bonding jumper installed for bonding two or more raceways or cables shall be sized in accordance with 250.102(C)(1).

Informational Note: The term supply conductors includes ungrounded conductors that do not have overcurrent protection on their supply side and terminate at service equipment or the first disconnecting means of a separately derived system.

</tbody>
</table>

Notes:

1. If multiple sets of service-entrance conductors are used as permitted in 230.40, Exception No. 2, or if multiple sets of ungrounded supply conductors are installed for a separately derived system, the equivalent size of the largest ungrounded supply conductor(s) shall be determined by the largest sum of the areas of the corresponding conductors of each set.

2. If there are no service-entrance conductors, the supply conductor size shall be determined by the equivalent size of the largest service-entrance conductor required for the load to be served.

3. If the ungrounded supply conductors are larger than 1100 kcmil copper or 1750 kcmil aluminum, the grounded conductor or bonding jumper shall have an area not less than 12 1/2 percent of the area of the largest ungrounded supply conductor or equivalent area for parallel supply conductors. The grounded conductor or bonding jumper shall not be required to be larger than the largest ungrounded conductor or set of ungrounded conductors.

4. If the ungrounded supply conductors are larger than 1100 kcmil copper or 1750 kcmil aluminum and if the ungrounded supply conductors and the bonding jumper are of different materials (copper, aluminum, or copper-clad aluminum), the minimum size of the grounded conductor or bonding jumper shall be based on the assumed use of ungrounded supply conductors of the same material as the grounded conductor or bonding jumper and will have an ampacity equivalent to that of the installed ungrounded supply conductors.

5. If multiple sets of service-entrance conductors are used as permitted in 230.40, Exception No. 2, or if multiple sets of ungrounded supply conductors are installed for a separately derived system, the equivalent size of the largest ungrounded supply conductor(s) shall be determined by the largest sum of the areas of the corresponding conductors of each set.

6. If there are no service-entrance conductors, the supply conductor size shall be determined by the equivalent size of the largest service-entrance conductor required for the load to be served.

*For the purposes of applying this table and its notes, the term bonding jumper refers to main bonding jumpers, system bonding jumpers, and supply-side bonding jumpers.

Informational Note: See Chapter 9, Table 8, for the circular mil area of conductors 18 AWG through 4/0 AWG.

Statement of Problem and Substantiation for Public Comment

Due to transcription errors the rearrangement and changes to the notes to Table 250.102(C)(1) did not reflect the panel action. See ballot comments from Charles Mello.

250.104 Bonding of Piping Systems and Exposed Structural Metal.

(A) Metal Water Piping.

The metal water piping system shall be bonded as required in (A)(1), (A)(2), or (A)(3) of this section.

(1) General.

Metal water piping system(s) installed in or attached to a building or structure shall be bonded to any of the following:

(1) Service equipment enclosure
(2) Grounded conductor at the service
(3) Grounding electrode conductor where of sufficient size
(4) One or more grounding electrodes used, if the grounding electrode conductor or bonding jumper to the grounding electrode is of sufficient size.

The bonding jumper(s) shall be sized in accordance with 250.64(A), 250.64(B), and 250.64(E). The points of attachment of the bonding jumper(s) shall be accessible. The bonding jumper(s) shall be sized in accordance with Table 250.66 except as permitted in 250.104(A)(2) and 250.104(A)(3).

(B) Buildings of Multiple Occupancy.

In buildings of multiple occupancy where the metal water piping system(s) installed in or attached to a building or structure for the individual occupancies is metallically isolated from all other occupancies by use of nonmetallic water piping, the metal water piping system(s) for each occupancy shall be permitted to be bonded to the equipment grounding terminal of the switchgear, switchboard, or panelboard enclosure (other than service equipment) supplying that occupancy. The equipment bonding jumper shall be sized in accordance with 250.102(D).

(C) Multiple Buildings or Structures Supplied by a Feeder(s) or Branch Circuit(s).

The metal water piping system(s) installed in or attached to a building or structure shall be bonded to any of the following:

(a) Building or structure disconnecting means enclosure where located at the building or structure
(b) Equipment grounding conductor run with the supply conductors
(c) One or more grounding electrodes used

The bonding jumper(s) shall be sized in accordance with Table 250.66, based on the size of the feeder or branch-circuit conductors that supply the building or structure. The bonding jumper shall not be required to be larger than the largest ungrounded feeder or branch-circuit conductor supplying the building or structure.

(B) Other Metal Piping.

If installed in or attached to a building or structure, a metal piping system(s), including gas piping, that is likely to become energized shall be bonded to any of the following:

(1) Equipment grounding conductor for the circuit that is likely to energize the piping system
(2) Service equipment enclosure
(3) Grounded conductor at the service
(4) Grounding electrode conductor, if of sufficient size
(5) One or more grounding electrodes used, if the grounding electrode conductor or bonding jumper to the grounding electrode is of sufficient size

The bonding conductor(s) or jumper(s) shall be sized in accordance with Table 250.122, and equipment grounding conductors shall be sized in accordance with Table 250.122 using the rating of the circuit that is likely to energize the piping system(s). The points of attachment of the bonding jumper(s) shall be accessible.

Informational Note No. 1: Bonding all piping and metal air ducts within the premises will provide additional safety.

Informational Note No. 2: Additional information for gas piping systems can be found in Section 7.13 of NFPA 54-2012, National Fuel Gas Code.
(C) Structural Metal.

Structural metal that is not intentionally grounded or bonded and is likely to become energized shall be bonded to any of the following:

1. Service equipment enclosure
2. Grounded conductor at the service
3. Disconnecting means for buildings or structures supplied by a feeder or branch circuit
4. Grounding electrode conductor, if of sufficient size
5. One or more grounding electrodes used, if the grounding electrode conductor or bonding jumper to the grounding electrode is of sufficient size

The bonding conductor(s) or jumper(s) shall be sized in accordance with Table 250.66, and shall be installed in accordance with 250.64(A), (B), and (E). The points of attachment of the bonding jumper(s) shall be accessible unless installed in compliance with 250.68(A) Exception No. 2.

(D) Separately Derived Systems.

Metal water piping systems and structural metal shall be bonded to separately derived systems in accordance with 250.104(D)(1) through 250.104(D)(3)

1. Metal Water Piping System(s).

The grounded conductor of each separately derived system shall be bonded to the nearest available point of the metal water piping system(s) in the area served by each separately derived system. This connection shall be made at the same point on the separately derived system where the grounding electrode conductor is connected. Each bonding jumper shall be sized in accordance with Table 250.66 based on the largest ungrounded conductor of the separately derived system.

Exception No. 1: A separate bonding jumper to the metal water piping system shall not be required where the metal water piping system is used as the grounding electrode for the separately derived system and the water piping system is in the area served.

Exception No. 2: A separate water piping bonding jumper shall not be required where the metal frame of a building or structure is used as the grounding electrode for a separately derived system and is bonded to the metal water piping in the area served by the separately derived system.

2. Structural Metal.

If exposed structural metal that is interconnected to form the building frame exists in the area served by the separately derived system, it shall be bonded to the grounded conductor of each separately derived system. This connection shall be made at the same point on the separately derived system where the grounding electrode conductor is connected. Each bonding jumper shall be sized in accordance with Table 250.66 based on the largest ungrounded conductor of the separately derived system.

Exception No. 1: A separate bonding jumper to the building structural metal shall not be required where the metal frame of a building or structure is used as the grounding electrode for the separately derived system.

Exception No. 2: A separate bonding jumper to the building structural metal shall not be required where the water piping of a building or structure is used as the grounding electrode for a separately derived system and is bonded to the building structural metal in the area served by the separately derived system.

Where a common grounding electrode conductor is installed for multiple separately derived systems as permitted by 250.30(A)(6), and structural metal or interior metal piping exists in the area served by the separately derived system, the metal piping and the structural metal member shall be bonded to the common grounding electrode conductor in the area served by the separately derived system.

Exception: A separate bonding jumper from each derived system to metal water piping and to structural metal members shall not be required where the metal water piping and the structural metal members in the area served by the separately derived system are bonded to the common grounding electrode conductor.

Statement of Problem and Substantiation for Public Comment

Submittal Date: Mon Sep 28 15:40:48 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-1220-NFPA 70-2015
Statement: Further consideration was given to the comments expressed in voting on FR 1216 in accordance with the direction of the Correlating Committee. It was determined that the intended Panel 5 revisions to 250.104 were not shown correctly in FR 1216. The proposed second revision corrects these transcription errors. The reference to NFPA 54 in Informational Note No. 2 in 250.104(B) was also updated. Also note that references to Table 250.66 were changed to Table 250.102(C)(1) in several locations as these conductors are bonding jumpers, not grounding electrode conductors.

In several locations, the word "where" was appropriately changed to "if".
Public Comment No. 165-NFPA 70-2015 [Section No. 250.104(B)]

(B) Other Metal Piping.
If installed in or attached to a building or structure, a metal piping system(s), including gas piping, that is likely to become energized shall be bonded to any of the following:

1. Equipment grounding conductor for the circuit that is likely to energize the piping system
2. Service equipment enclosure
3. Grounded conductor at the service
4. Grounding electrode conductor, if of sufficient size
5. One or more grounding electrodes used, if the grounding electrode conductor or bonding jumper to the grounding electrode is of sufficient size

The bonding conductor(s) or jumper(s) shall be sized in accordance with Table 250.122, and equipment grounding conductors shall be sized in accordance with Table 250.122 using the rating of the circuit that is likely to energize the piping system(s). The points of attachment of the bonding jumper(s) shall be accessible.

Informational Note No. 1: Bonding all piping and metal air ducts within the premises will provide additional safety.

Informational Note No. 2: Additional information for gas piping systems can be found in Section 7.13 of NFPA 54-2012 [2015], National Fuel Gas Code.

Committee Action: Rejected but see related SR
Resolution: SR-1220-NFPA 70-2015
Statement: Further consideration was given to the comments expressed in voting on FR 1216 in accordance with the direction of the Correlating Committee. It was determined that the intended Panel 5 revisions to 250.104 were not shown correctly in FR 1216. The proposed second revision corrects these transcription errors. The reference to NFPA 54 in Informational Note No. 2 in 250.104(B) was also updated. Also note that references to Table 250.68 were changed to Table 250.102(C)(1) in several locations as these conductors are bonding jumpers, not grounding electrode conductors.

In several locations, the word "where" was appropriately changed to "if".
Public Comment No. 336-NFPA 70-2015 [Section No. 250.104(C)]

(C) Structural Metal.

Structural metal that is interconnected to form a building frame and that is not intentionally grounded or bonded and is likely to become energized shall be bonded to any of the following:

1. Service equipment enclosure
2. Grounded conductor at the service
3. Disconnecting means for buildings or structures supplied by a feeder or branch circuit
4. Grounding electrode conductor, if of sufficient size
5. One or more grounding electrodes used, if the grounding electrode conductor or bonding jumper to the grounding electrode is of sufficient size

The bonding conductor(s) or jumper(s) shall be sized in accordance with Table 250.66 and installed in accordance with 250.64(A), (B), and (E). The points of attachment of the bonding jumper(s) shall be accessible unless installed in compliance with 250.68(A) Exception No. 2.

Statement of Problem and Substantiation for Public Comment

The deletion of the requirement that the structural metal be interconnected to form a frame results in a major expansion of this section without any substantiation. Without those words a single steel beam in a dwelling unit basement or the metal bar joists in a commercial block wall building will require a bonding connections.

Statement of Problem and Substantiation for Public Comment

Structural steel that is ‘grounded’ is not going to clear a ground-fault (you guys know that), and adding if bonded to the rule just adds confusion. How about we follow the same rule for all of 250.104 parts like we did in (A) and (B). Let’s keep it safe, let’s not go back to 2005 language (when grounding was considered safe from a ground fault).

Submittal Date: Tue Aug 04 16:52:16 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: Structural metal likely to become energized is required to be bonded. This section further clarifies that if the structural metal has already been grounded or bonded, it is not required to be bonded again.
Metal water piping systems and structural metal that is interconnected to form a building frame shall be bonded to separately derived systems in accordance with 250.104(D)(1) through 250.104(D)(3).

Statement of Problem and Substantiation for Public Comment

The proposed wording is a major expansion of the bonding requirements that was made without any substantiation. The new wording requires any structural metal, such as a single bean or things like bar joist to be bonded. This same change also needs to be made in 250.104(D)(2).

The reference to NFPA 54 in Informational Note No. 2 in 250.104(B) was also updated. Also note that references to Table 250.66 were changed to Table 250.102(C)(1) in several locations as these conductors are bonding jumpers, not grounding electrode conductors.

In several locations, the word "where" was appropriately changed to "if".
(B) Multiconductor Cable.

One. Where the conditions of maintenance and supervision ensure that only qualified persons service the installation, one or more insulated conductors in a multiconductor cable, at the time of installation, shall be permitted to be permanently identified as equipment grounding conductors at each end and at every point where the conductors are accessible by one of the following means:

1. Stripping the insulation from the entire exposed length
2. Coloring the exposed insulation green
3. Marking the exposed insulation with green tape or green adhesive labels. Identification shall encircle the conductor.

Statement of Problem and Substantiation for Public Comment

Removal of the requirements for conditions of maintenance and supervision by qualified persons is a reduction of safety for re-identification of the most important safety conductor in a multiconductor cable. The panel statement cites consistency with 200.7(C) which permits the grounded conductor to be re-identified as an ungrounded conductor, however, it is not consistent with the more important requirement of 200.6(E) which in general requires the grounded conductor to be a continuous white or gray outer finish in a multiconductor cable. Additionally, the exception in 200.6(E) remains, as it should, permitting re-identification only in locations where conditions of maintenance and supervision ensure only qualified persons service the installation. 250.119(B) needs to be consistent with 200.6(E) and not 200.7(C). Re-identifying conductors, whether for equipment grounding conductors, grounded conductors, or as permitted in 200.7(C) for ungrounded conductors in multiconductor cables is often missed and violated especially by installers who are other than qualified. Manufactures make and have readily available the correct multiconductor cable for installations with properly identified equipment grounding conductors which should be used in place of an incorrect cable being used for an application it was not originally manufactured.

Returning this portion of the text to previous edition will maintain consistency with 200.6(E).
Delete the changes as edited in FR 1230 and revert to the existing 2014 language as follows:

(B) Multiconductor Cable.

One

Where the conditions of maintenance and supervision ensure that only qualified persons service the installation, one or more insulated conductors in a multiconductor cable, at the time of installation, shall be permitted to be permanently identified as equipment grounding conductors at each end and at every point where the conductors are accessible by one of the following means:

(1) Stripping the insulation from the entire exposed length
(2) Coloring the exposed insulation green
(3) Marking the exposed insulation with green tape or green adhesive labels. Identification shall encircle the conductor.

Statement of Problem and Substantiation for Public Comment

The panel action on this PI should have been a resolve. The edit made to sub-part (B) of this section removes the limited application (originally an exception) of identifying those colors that are traditionally associated with ungrounded conductors to the color green. This now provides unrestricted re-identification of said colored conductors (black blue etc.) in all multi-wire cables in all locations as an equipment grounding conductor. Field makings are a moving target. This expanded permissive language for conductors 6 AWG and smaller, can create a problem over time which will be exponentially increased, especially in locations where premises maintenance is not limited to those who are familiar with local marking procedures (such as an industrial location). One argument expressed during panel discussion included a reference to the language found in section 200.7 regarding re-identification and use of a white (or gray) conductor as an ungrounded conductor. This is understandable, but in reality if a re-identified white conductor was inadvertently connected to a grounded terminal or an energized terminal the failure would be limited to one branch circuit or feeder. A mistake with a conductor that is intentionally connected to the system or structures non-current carrying metal parts is life threatening and may raise the potential on the entire structure presenting a shock hazard (or worse). This hazard might migrate to other systems (such as chapter 8 wiring) that are permitted to be terminated to the structures intersystem bond terminals as mentioned in 250.94. Once this permissive rule is extended to residential and commercial occupancies where the lion share of the work is performed by pedestrian installers having no stake in the continued and safe operation of the facility or dwelling the monitoring of that installation and its future.

Statement of Problem and Substantiation for Public Comment

Sealed wire connection systems are not listed for outdoor exposure and does not protect conductor material. The sealed system is not listed for UV exposure. Such use would violate the UL listing. The term "suitable" is not recognized or defined. The submitter has not provided any substantiating evidence that the change is allowable or warranted. There is no reason to change the Code.

Public Comment No. 791-NFPA 70-2015 [Section No. 250.120(B)]

(B) Aluminum and Copper-Clad Aluminum Conductors.

Equipment grounding conductors of bare or insulated aluminum or copper-clad aluminum shall be permitted. Bare conductors shall not come in direct contact with masonry or the earth or where subject to corrosive conditions. Aluminum or copper-clad aluminum conductors shall not be terminated within 450 mm (18 in.) of the earth, unless the termination method is listed as a sealed wire-connector system. Terminations made within listed enclosures suitable for outdoor use shall be permitted within 18 in. of the earth.

Statement of Problem and Substantiation for Public Comment

This section permits bare aluminum equipment grounding conductors. Listed sealed wire connection systems have not been evaluated for sealing of bare or uninsulated conductors. The following information is from the UL White Book in ZMWQ:

This category covers sealed wire-connector systems intended for wet or damp locations and other installations, such as direct burial, below grade, or above grade where protected from direct exposure to sunlight. These systems may also be used indoors or in dry locations.

Sealed wire-connector systems are intended for use in installations covered by ANSI/NFPA 70, "National Electrical Code."

Sealed wire-connector systems have not been investigated for direct exposure to sunlight. Additional performance considerations to show equivalency to the connected conductors should be considered for UV exposure.

Sealed wire-connector systems have not been investigated for direct exposure to salt or seawater.

This category covers a complete system or insulating caps, covers, resins, tubing and tapes that are part of the system for use with specific wire connectors where the seal is made at the conductor. Pressure wire connectors may or may not be provided with the system.

In addition, the phrase in the last sentence relative to the use of the term "suitable" is inappropriate and not defined in the NEC. This substantiates the deletion of the last sentence.

Committee Action: Rejected but see related SR
Resolution: SR-1222-NFPA 70-2015
Statement: Revisions were made to add covered conductors to provide requirements for their use. The revisions clarify the use of sealed wire connector systems and outdoor enclosures. The text is rewritten in list format to improve clarity.
(B) Increased in Size.

If ungrounded conductors are increased in size for any reason from the minimum size that has sufficient ampacity for the intended installation before the application of any adjustment or correction factor(s), required wire-type equipment grounding conductors shall be increased in size. The increase in size shall be in the same proportion as the proportionate to the increase in the size of the ungrounded conductors using their circular mil area conductor(s), calculated using circular mil areas or AWG size changes.

Statement of Problem and Substantiation for Public Comment

Adding the word "required" takes into consideration metallic wiring methods which qualify as an equipment grounding conductor without the addition of a wire-type EGC. Such systems employing a "redundant" wire-type EGC have already been upsized. Direct upsizing to non-metallic wiring methods where upsizing is necessary.

Also, when economics are a major design consideration, specifiers may opt to just not include a wire-type EGC in EGC-qualifying metallic wiring methods rather than upsize. Better to install a minimum-sized wire-type EGC than none at all.

Also added that proportionate sizing can be determined by AWG size changes, i.e. a change of 4 AWG sizes is proportional no matter what two sizes you start with. See Public Comment No. 81 and related Input.

This revision was suggested by a ballot comment in the First Draft.
Public Comment No. 338-NFPA 70-2015 [Section No. 250.122(B)]

(B) Increased in Size.

If ungrounded conductors are increased in size for any reason from the minimum size that has sufficient ampacity for the intended installation before the application of any adjustment or correction factor(s), wire-type equipment grounding conductors shall be increased in size. The minimum size of the ungrounded conductors shall be the allowable ampacity per the Tables in 310.15(B). The increase in size shall be in the same proportion as the increase in the size of the ungrounded conductors using their circular mil area.

Statement of Problem and Substantiation for Public Comment

It appears to me that the basis for the increase in size of the EGC is the allowable ampacities as found in the 310.15(B) tables. This change make that clear.

This revision was suggested by a ballot comment in the First Draft.
(B) Increased in Size.
If ungrounded conductors are increased in size for any reason from the minimum size that has sufficient ampacity for the intended installation before the application of any adjustment or correction factor(s), wire-type equipment grounding conductors shall be increased in size. The increase in size shall be in the same proportion as, to, or greater than, the increase in the size of the ungrounded conductors using their circular mil area.

Statement of Problem and Substantiation for Public Comment
It's probably not going to be possible to get an exact match to the proportional increase of the current carrying conductors in the EGC. The EGC should be equal to, or greater than, the proportional increase.

Submittal Date: Sun Sep 20 18:06:36 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-1223-NFPA 70-2015
Statement: Increase of the equipment grounding conductor size due to adjustment or correction factors is not necessary because of the short duration of a fault.

This revision was suggested by a ballot comment in the First Draft.
(B) Increased in Size.

If ungrounded conductors are increased in size for any reason from the minimum size that has sufficient ampacity for the intended installation before the application of any adjustment or correction factor(s), wire-type equipment grounding conductors shall be increased in size. The increase in size shall be in the same proportion as the increase in the size of the ungrounded conductors using their circular mil area.

Informational Note: Circular mil areas of AWG sized conductors are rounded to four significant figures per ASTM B258 Standard Specification for Standard Nominal Diameters and Cross-Sectional Areas of AWG Sizes of Solid Round Wires Used as Electrical Conductors. Proportion calculation should adhere to ASTM E29 Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications, specifically §7.4.1.2 which states, "The rule when multiplying or dividing is that the result shall contain no more significant digits than the value with the smaller number of significant digits." As such, an equal change in AWG number satisfies the proportion requirement. For example, an ungrounded conductor increased from 3AWG to 2/0AWG (a change of 4) is the same increase in circular mil area proportion as an equipment grounding conductor increased from 8AWG to 4AWG (also a change of 4).

Statement of Problem and Substantiation for Public Comment

Resolution to Public Input No. 1111 states, "The informational note is misleading for some conditions and does not provide clarity for correctly sizing the EGC necessary to carry fault current." Without additional comment, there is no way for me to determine in what way and how my proposed Informational Note is misleading in some conditions and lacks clarity for correctly sizing the EGC. The proposed Informational Note is about calculating proportion, nothing else. I therefore submit full blown text for the Informational Note to provide more clarity. I cannot fathom any condition for which this Informational Note would be misleading. Please be more specific in any and all committee statements in this regard.

I do not have copyright permission to include ASTM B258 or ASTM E29 herewith as supporting documents.

Committee Statement

Committee Action: Rejected
Resolution: The informational note suggested did not add clarity and does not include stranding types other than round.
Conductors in Parallel.

For circuits of parallel conductors as permitted in 310.10(H), the equipment grounding conductor shall be installed in accordance with (1) or (2). The equipment grounding conductor shall not be required to be larger than the largest ungrounded conductor within the raceway or cable.

(1) Conductor Installations in Raceways, Auxiliary Gutters, or Cable Trays

(a) Single Raceway or Cable Tray. If conductors are installed in parallel in the same raceway or cable trays a single wire type conductor shall be permitted as the equipment grounding conductor. The wire type equipment grounding conductor shall be sized in accordance with 250.122. Wire type equipment grounding conductors installed in cable trays shall meet the minimum requirements of 392.10(B)(1)(c). Cable trays complying with 392.60(B), metal raceways in accordance with 250.118, or auxiliary gutters, shall be permitted as the equipment grounding conductor.

(b) Multiple Raceways. If conductors are installed in parallel in multiple raceways, wire type equipment grounding conductors, where used, shall be installed in parallel in each raceway. The equipment grounding conductor installed in each raceway shall be sized in compliance with 250.122. Cable trays complying with 392.60(B), metal raceways in accordance with 250.118, or auxiliary gutters, shall be permitted as the equipment grounding conductor.

(2) Multiconductor Cables

(a) If multiconductor cables are installed in parallel, the equipment grounding conductor(s) in each cable shall be connected in parallel. Except as provided in 250.122(F)(2)(b) for raceway or cable tray installations, the equipment grounding conductor in each multiconductor cable shall be sized in accordance with 250.122.

(b) If multiconductor cables are installed in parallel in the same raceway, auxiliary gutter, or cable tray, a single equipment grounding conductor that is sized in accordance with 250.122 shall be permitted in combination with the equipment grounding conductors provided within the multiconductor cables and shall all be connected together. Equipment grounding conductors installed in cable trays shall meet the minimum requirements of 392.10(B)(1)(c). Cable trays complying with 392.60(B), metal raceways in accordance with 250.118, or auxiliary gutters, shall be permitted as the equipment grounding conductor.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs that further consideration be given to the comments expressed in voting on FR 1236. The text of FR 1236 as written is run-on and confusing.

Submittal Date: Mon Sep 28 15:45:40 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-1224-NFPA 70-2015
Statement: The panel has reviewed the Correlating Committee comment and has split 250.122(F)(2) into (2)(a), (b), (c), and (d) to make the text easier to understand.
For circuits of parallel conductors as permitted in 310.10(H), the equipment grounding conductor shall be installed in accordance with (1) or (2). The equipment grounding conductor shall not be required to be larger than the largest ungrounded conductor within the raceway or cable.

Statement of Problem and Substantiation for Public Comment

The sentence "The equipment grounding conductor shall not be required to be larger than the largest ungrounded conductor within the raceway or cable." should be deleted. The implication is that this is a clarification of the requirement in 250.122(A) that states "... but in no case shall they be required to be larger than the circuit conductors supplying the equipment." The proposed new sentence in 250.122(F) conflicts with 250.122(A) and adds confusion in applying the provisions of this section. This was proposed for the 2014 Edition of the NEC and was held for the next Edition. There were statements that no documentation or substantiation was submitted to justify this change, and none was offered for the 2017 Edition. The Panel 5 Task Group assigned this PI recommended resolve.

In some cases, compliance with the proposed new sentence could result in an electrically hazardous situation: Since 1/0 AL conductors are allowed to be paralleled, several could be installed in parallel to give an ampacity of 960 amperes. Some overcurrent device equal to or less than 960 amperes could be used to protect the conductors. According to several sources, and per calculations, 1/0 AL conductors are suitable for fault currents up to approximately 36kA for one cycle and approximately 57kA for a half cycle. Many electrical systems are capable of delivering fault currents in excess of these values, and under some conditions, a portion of a single grounding conductor may be subjected to the entire fault energy, introducing the possibility of cable failure before the overcurrent device operates, resulting in dangerous voltages being imposed on exposed metallic components of the electrical system.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-1225-NFPA 70-2015
Statement: There was insufficient technical justification to insert the deleted sentence in the First Draft.
Conductor Installations in Raceways, Auxiliary Gutters, or Cable Trays

(a) Single Raceway or Cable Tray. If conductors are installed in parallel in the same raceway, or cable trays a single wire type conductor shall be permitted as the equipment grounding conductor. The wire type equipment grounding conductor shall be sized in accordance with 250.122. Wire type equipment grounding conductors installed in cable trays shall meet the minimum requirements of 392.10(B)(1) (c). Cable trays complying with 392.60(B), metal raceways in accordance with 250.118, or auxiliary gutters, shall be permitted as the equipment grounding conductor.

(b) Multiple Raceways. If conductors are installed in parallel in multiple raceways, wire type equipment grounding conductors, where used, shall be installed in parallel in each raceway. The equipment grounding conductor installed in each raceway shall be sized in compliance with 250.122. Cable trays complying with 392.60(B), metal raceways in accordance with 250.118, or auxiliary gutters, shall be permitted as the equipment grounding conductor. Where metallic raceways are used and are equipment grounding conductors per 250.118, an equipment grounding conductor of the wire type installed within each raceway shall not be required to be larger than what would be required for the largest overcurrent protective device that would be permitted to protect the conductors in the raceways.

Statement of Problem and Substantiation for Public Comment

The currently accepted version of this rule will result in designers and installers deleting an EGC of the wire type where the circuits are installed in metallic raceways. My change would also put raceways on a more equal footing with the change made for cables in 250.122(F)(2)(b).

Statement: The text is revised to correct transcription errors in the First Revision and to reflect the panel action in the First Revision meeting.
Public Comment No. 245-NFPA 70-2015 [Section No. 250.148 [Excluding any Sub-Sections]]

Where circuit conductors are spliced within a contained within an otherwise unbonded metal box, or spliced within or terminated on equipment within or supported by a box, all equipment grounding conductor(s) associated with any of those circuit conductors shall be connected, together, and/or bonded to the box if metal, with devices suitable for the use in accordance with 250.8 and 250.148(A) through (E).

Exception: The equipment grounding conductor permitted in 250.146(D) shall not be required to be connected to the other equipment grounding conductors or to the box.

Statement of Problem and Substantiation for Public Comment

Eliminates the ambiguity equipment grounding conductors being being associated certain circuit conductors. It is obviously associated with one or more circuit conductors, but if all [normal] EGC’s are to be connected together, the circuit to which an EGC is associated is irrelevant.

Also clarifies where a box is otherwise unbonded, it shall be bonded with the EGC’s, which should include the largest. Under the former text, one could have multiple sets of 500kcmil conductor running through a metal box unspliced, and yet have one #12 circuit spliced... and only a #12 bonding jumper would be required to the otherwise unbonded box. The alternative would be running a separate bonding jumper, but that does not adhere to the concept of grounding continuity.

Committee Statement

Committee Action: Rejected
Resolution: The panel reaffirms the previous decision that, where all the conductors of a circuit pass through the box or enclosure without splice or termination, the associated equipment grounding conductor(s) is not required to be spliced or connected to the other equipment grounding conductors or to the box or enclosure.
250.186. Grounding Service-Supplied Alternating-Current Systems of over 1000 Volts

(A) Systems with a Grounded Conductor at the Service Point.

Where an ac system is grounded at any point and is provided with a grounded conductor at the service point, a grounded conductor(s) shall be installed and routed with the ungrounded conductors to each service disconnecting means and shall be connected to each disconnecting means grounded conductor(s) terminal or bus. A main bonding jumper shall connect the grounded conductor(s) to each service disconnecting means's enclosure. The grounded conductor(s) shall be installed in accordance with 250.186(A)(1) through (A)(4). The size of the solidly grounded circuit conductor(s) shall be the larger of that determined by 250.184 or 250.186(A)(1) or (A)(2).

Exception: Where two or more service disconnecting means are located in a single assembly listed for use as service equipment, it shall be permitted to connect the grounded conductor(s) to the assembly common grounded conductor(s) terminal or bus. The assembly shall include a main bonding jumper for connecting the grounded conductor(s) to the assembly enclosure.

(1) Sizing for a Single Raceway or Overhead Conductor.

The grounded conductor shall not be smaller than the required grounding electrode conductor specified in Table 250.102(C)(1) but shall not be required to be larger than the largest ungrounded service-entrance conductor(s).

(2) Parallel Conductors in Two or More Raceways or Overhead Conductors.

If the ungrounded service-entrance conductors are installed in parallel in two or more raceways or as overhead parallel conductors, the grounded conductors shall also be installed in parallel. The size of the grounded conductor in each raceway or overhead shall be based on the total circular mil area of the parallel ungrounded conductors in the raceway or overhead, as indicated in 250.186(A)(1), but not smaller than 1/0 AWG.

Informational Note: See 310.10(H) for grounded conductors connected in parallel.

(3) Delta-Connected Service.

The grounded conductor of a 3-phase, 3-wire delta service shall have an ampacity not less than that of the ungrounded conductors.

(4) Impedance Grounded Neutral Systems.

Impedance grounded neutral systems shall be installed in accordance with 250.187.

(B) Systems Without a Grounded Conductor at the Service Point.

Where an ac system is grounded at any point and is not provided with a grounded conductor at the service point, a supply-side bonding jumper shall be installed and routed with the ungrounded conductors to each service disconnecting means and shall be connected to each disconnecting means equipment grounding conductor terminal or bus. The supply-side bonding jumper shall be installed in accordance with 250.186(B)(1) through (B)(3).

Exception: Where two or more service disconnecting means are located in a single assembly listed for use as service equipment, it shall be permitted to connect the supply-side bonding jumper to the assembly common equipment grounding terminal or bus.

(1) Sizing for a Single Raceway or Overhead Conductor.

The supply-side bonding jumper shall not be smaller than the required grounding electrode conductor specified in Table 250.102(C)(1) but shall not be required to be larger than the largest ungrounded service-entrance conductor(s).

(2) Parallel Conductors in Two or More Raceways or Overhead Conductors.

If the ungrounded service-entrance conductors are installed in parallel in two or more raceways or overhead conductors, the supply-side bonding jumper shall also be installed in parallel. The size of the supply-side bonding jumper in each raceway or overhead shall be based on the total circular mil area of the parallel ungrounded conductors in the raceway or overhead, as indicated in 250.186(A)(1), but not smaller than 1/0 AWG.

(3) Impedance Grounded Neutral Systems.

Impedance grounded neutral systems shall be installed in accordance with 250.187.

Statement of Problem and Substantiation for Public Comment

Due to transcription errors the Draft did not reflect the panel action. See ballot comments from Charles Mello.

250.186  Grounding Service-Supplied Alternating-Current Systems of over 1000 Volts

(A) Systems with a Grounded Conductor at the Service Point.

Where an ac system is grounded at any point and is provided with a grounded conductor at the service point, a grounded conductor(s) shall be installed and routed with the ungrounded conductors to each service disconnecting means and shall be connected to each disconnecting means grounded conductor(s) terminal or bus. A main bonding jumper shall connect the grounded conductor(s) to each service disconnecting means's enclosure. The grounded conductor(s) shall be installed in accordance with 250.186(A)(1) through (A)(4). The size of the solidly grounded circuit conductor(s) shall be the larger of that determined by 250.184 or 250.186(A)(1) or (A)(2).

Exception: Where two or more service disconnecting means are located in a single assembly listed for use as service equipment, it shall be permitted to connect the grounded conductor(s) to the assembly common grounded conductor(s) terminal or bus. The assembly shall include a main bonding jumper for connecting the grounded conductor(s) to the assembly enclosure.

(1) Sizing for a Single Raceway or Overhead Conductor.

The grounded conductor shall not be smaller than the required grounding electrode conductor specified in Table 250.102(C)(1) but shall not be required to be larger than the largest ungrounded service-entrance conductor(s).

(2) Parallel Conductors in Two or More Raceways or Overhead Conductors.

If the ungrounded service-entrance conductors are installed in parallel in two or more raceways or as overhead parallel conductors, the grounded conductors shall also be installed in parallel. The size of the grounded conductor in each raceway or overhead shall be based on the total circular mil area of the parallel ungrounded conductors in the raceway or overhead, as indicated in 250.186(A)(1), but not smaller than 1/0 AWG.

Informational Note: See 310.10(H) for grounded conductors connected in parallel.

(3) Delta-Connected Service.

The grounded conductor of a 3-phase, 3-wire delta service shall have an ampacity not less than that of the ungrounded conductors.

(4) Impedance Grounded Neutral Systems.

Impedance grounded neutral systems shall be installed in accordance with 250.187.

(B) Systems Without a Grounded Conductor at the Service Point.

Where an ac system is grounded at any point and is not provided with a grounded conductor at the service point, a supply-side bonding jumper shall be installed and routed with the ungrounded conductors to each service disconnecting means and shall be connected to each disconnecting means equipment grounding conductor terminal or bus. The supply-side bonding jumper shall be installed in accordance with 250.186(B)(1) through (B)(3).

Exception: Where two or more service disconnecting means are located in a single assembly listed for use as service equipment, it shall be permitted to connect the supply-side bonding jumper to the assembly common equipment grounding terminal or bus.

(1) Sizing for a Single Raceway or Overhead Conductor.

The supply-side bonding jumper shall not be smaller than the required grounding electrode conductor specified in Table 250.102(C)(1) but shall not be required to be larger than the largest ungrounded service-entrance conductor(s).

(2) Parallel Conductors in Two or More Raceways or Overhead Conductors.

If the ungrounded service-entrance conductors are installed in parallel in two or more raceways or overhead conductors, the supply-side bonding jumper shall also be installed in parallel. The size of the supply-side bonding jumper in each raceway or overhead shall be based on the total circular mil area of the parallel ungrounded conductors in the raceway or overhead, as indicated in 250.186(A)(1), but not smaller than 1/0 AWG.

(3) Impedance Grounded Neutral Systems.

Impedance grounded neutral systems shall be installed in accordance with 250.187.

Statement of Problem and Substantiation for Public Comment

Public Comment No. 1404-NFPA 70-2015 [ Section No. 250.187(B) ]

(B) Identified and Insulated.

The neutral conductor of an impedance grounded neutral system shall be identified. For high resistance grounded systems, as well as fully insulated for the maximum, the neutral shall have the same insulation rating as the phase conductors. For other systems, the neutral shall be permitted to have insulation rating of not less than the maximum line to neutral voltage.

Statement of Problem and Substantiation for Public Comment

In doing research on reducing the insulation rating on the neutral for the impedance grounded systems over 1000 volts, I found two articles, EC&M (Electrical Construction & Maintenance) April 1, 2007 "From the Ground Up" written by Tony Locker, P.E., I-Gard and "Resistance Grounding System Basics" written by Michael D. Seal, P.E., G.E. Senior Specifications Engineer, containing similar viewpoints on the requirements for the insulation rating of the neutral. To paraphrase, both effectively state that in a ground-fault event with one phase faulted, the system operates with the un-faulted phases being raised from earth potential to the full phase-to-phase voltage for an extended period. Therefore the insulation system needs to be rated for phase-to-phase voltage. In the first article cited, the author applies this thought to the high resistance grounded systems which he also cites as being typically used in less than 5 kV applications. Additionally, in both PI-1798 and FR-7525 reference is made to the neutral voltage being 57.7% of the system voltage. This is true strictly for a three-phase wye system. If it is also possible to have a three-phase delta system operated with an impedance grounded neutral system, then the 57.7% would be inaccurate and the reason for clarifying in the Code the maximum line to neutral voltage for other systems such as low resistance grounded systems and resonance grounded systems.

Submitter Information Verification

Submitter Full Name: Derrick Atkins
Organization:
Street Address:
City:
State:
Zip:
Submittal Date: Fri Sep 25 10:14:53 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-1229-NFPA 70-2015 The phase to neutral voltage, as provided in the FR, would only apply to three phase wye systems. It is technically infeasible for the neutral to ground voltage to exceed the 57.7 percent of the phase-to-phase voltage. There is no need to repeat the application for impedance grounded system, as the section is for this type of system only.
Statement: The formatting revisions improve clarity. By establishing the list items, this provides enforcement clearer statement for defining any corrections required.

An informational note was added to clarify the magnitude of the neutral voltage.
250.191  Grounding System at Alternating-Current Substations.
For ac substations, the grounding system shall be in accordance with Part III of Article 250.

250.194 - Grounding and Bonding of Fences and Other Metal Structures.

Metallic fences enclosing, and other metal structures in or surrounding, a substation with exposed electrical conductors and equipment shall be grounded and bonded to limit step, touch, and transfer voltages.

(A) Metal Fences.

Where metal fences are located within 5 m (16 ft) of the exposed electrical conductors or equipment, the fence shall be bonded to the grounding electrode system with wire-type bonding jumpers as follows:

1. Bonding jumpers shall be installed at each fence corner and at maximum 50 m (160 ft) intervals along the fence.
2. Where bare overhead conductors cross the fence, bonding jumpers shall be installed on each side of the crossing.
3. Gates shall be bonded to the gate support post, and each gate support post shall be bonded to the grounding electrode system.
4. Any gate or other opening in the fence shall be bonded across the opening by a buried bonding jumper.
5. The grounding grid or grounding electrode systems shall be extended to cover the swing of all gates.
6. The barbed wire strands above the fence shall be bonded to the grounding electrode system.

Alternate designs performed under engineering supervision shall be permitted for grounding or bonding of metal fences.

Informational Note No. 1: A nonconducting fence or section may provide isolation for transfer of voltage to other areas.

(B) Metal Structures.

All exposed conductive metal structures, including guy wires within 2.5 m (8 ft) vertically or 5 m (16 ft) horizontally of exposed conductors or equipment and subject to contact by persons, shall be bonded to the grounding electrode systems in the area.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-1231-NFPA 70-2015
Statement: The revision updates the reference in the informational note to the current edition of the standard.
280.1 Scope.
This article covers general requirements, installation requirements, and connection requirements for surge arresters installed on premises wiring systems over 2000 over 1000 volts.

Statement of Problem and Substantiation for Public Comment
The voltage level should remain at 1000 volts. Making the change to 2000 volts may allow additional items to comply with low voltage requirements without substantiation and may create safety issues. Although the change in voltage does not directly impact the grounding requirements in Article 250, it creates inconsistency with other Articles throughout the code, as other CMP’s did not accept these Public Inputs.

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-1232-NFPA 70-2015
Statement: There is inadequate technical substantiation to increase this to 2000 volts at this time.
280.4 Surge Arrester Selection.
The surge arresters shall comply with 280.4(A) and (B).

(A) Rating.
The rating of a surge arrester shall be equal to or greater than the maximum continuous operating voltage available at the point of application.

(2) Solidly Grounded Systems.
The maximum continuous operating voltage shall be the phase-to-ground voltage of the system.

(3) Impedance or Ungrounded System.
The maximum continuous operating voltage shall be the phase-to-phase voltage of the system.

(D) Silicon Carbide Types.
The rating of a silicon carbide-type surge arrester shall be not less than 125 percent of the rating specified in 280.4(A).

Informational Note No. 2: The selection of a properly rated metal oxide arrester is based on considerations of maximum continuous operating voltage and the magnitude and duration of overvoltages at the arrester location as affected by phase-to-ground faults, system grounding techniques, switching surges, and other causes. See the manufacturer's application rules for selection of the specific arrester to be used at a particular location.

Resolution: SR-1234-NFPA 70-2015
Statement: The panel reviewed the text as directed by the Correlating Committee. The revised text clarifies the intent of the panel.
280.24 Interconnections.

The surge arrester protecting a transformer that supplies a secondary distribution system shall be interconnected as specified in 280.24(A), (B), or (C).

(A) Metal Interconnections.

A metal interconnection shall be made to the secondary grounded circuit conductor or the secondary circuit grounding electrode conductor, if, in addition to the direct grounding connection at the surge arrester, the following occurs:

(1) Additional Grounding Connection. The grounded conductor of the secondary has elsewhere a grounding connection to a continuous metal underground water piping system. In urban water-pipe areas where there are at least four water-pipe connections on the neutral conductor and not fewer than four such connections in each mile of neutral conductor, the metallic interconnection shall be permitted to be made to the secondary neutral conductor with omission of the direct grounding connection at the surge arrester.

(2) Multigrounded Neutral System Connection. The grounded conductor of the secondary system is a part of a multigrounded neutral system or static wire of which the primary neutral conductor or static wire has at least four grounding connections in each mile of line in addition to a grounding connection at each service.

(B) Through Spark Gap or Device.

Where the surge arrester grounding electrode conductor is not connected as in 280.24(A), or where the secondary is not grounded as in 280.24(A) but is otherwise grounded as in 250.52, an interconnection shall be made through a spark gap or listed device as required by 280.24(B)(1) or (B)(2).

(1) Ungrounded or Unigrounded Primary System. For ungrounded or unigrounded primary systems, the spark gap or listed device shall have a 60-Hz breakdown voltage of at least twice the primary circuit voltage but not necessarily more than 10 kV, and there shall be at least one other ground on the grounded conductor of the secondary that is not less than 6.0 m (20 ft) distant from the surge-arrester grounding electrode.

(2) Multigrounded Neutral Primary System. For multigrounded neutral primary systems, the spark gap or listed device shall have a 60-Hz breakdown of not more than 3 kV, and there shall be at least one other ground on the grounded conductor of the secondary that is not less than 6.0 m (20 ft) distant from the surge-arrester grounding electrode.

(C) By Special Permission.

An interconnection of the surge-arrester ground and the secondary neutral conductor, other than as provided in 280.24(A) or (B), shall be permitted to be made only by special permission.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-1236-NFPA 70-2015
Statement: There is inadequate technical substantiation to increase this to 2000 volts at this time.
Public Comment No. 9-NFPA 70-2015 [Section No. 285.1]

285.1 Scope.

This article covers general requirements, installation requirements, and connection requirements for surge-protective devices (SPDs) permanently installed on premises wiring systems of 2000-1000 volts or less.

Informational Note: Surge arresters 2000-1000 volts or less are also known as Type 1 SPDs.

Statement of Problem and Substantiation for Public Comment

The problem is that the existing ANSI/UL 1449-2014 standard only covers surge protective devices (SPD) up to 1000 Vac in its scope. So, there is no technical standard that can "list" an SPD beyond 1000 Vac. Allowing voltages beyond 1000 without a possible "listing" violates section 285.5 requiring a "listed" device.

As a working group member of UL 1449 and the IEEE PES Surge Protective Device (3.6) committees, there is no technical nor product-safety direction yet established by these standards committees. Therefore, I have even greater reluctance toward the NEC including voltages beyond 1000 Vac. Without a solid product-safety standard to address SPDs between 1000 and 2000 Vac, the NFPA should not change the 285.1

In reality, the ANSI C84 standard does not recognize any low-voltage electrical system beyond 600 volts. We do know that Wind Turbines deliver a 690Y/400 V system - this is unique to these systems. Therefore, even stating "up to 1000 V" is more than what is covered in other standards.

The fact that the C84.1-2011 standard remains nebulous between 600 and 2400 volts should also cause the NFPA pause as well.

Keeping the maximum voltage at 1000 volts maintains code consistency with the change to up the low voltage range from 600 to 1000 volts.

Resolution: SR-1236-NFPA 70-2015
Statement: There is inadequate technical substantiation to increase this to 2000 volts at this time.
285.3 Uses Not Permitted.
An SPD device shall not be installed in the following:

1. Circuits over **2000 - 1000** volts
2. On ungrounded systems, impedance grounded systems, or corner grounded delta systems unless listed specifically for use on these systems
3. Where the rating of the SPD is less than the maximum continuous phase-to-ground power frequency voltage available at the point of application

Statement of Problem and Substantiation for Public Comment

This also relates to comments made to 285.1.

The problem is that the existing ANSI/UL 1449-2014 standard only covers surge protective devices (SPD) up to 1000 Vac in its scope. So, there is no technical standard that can "list" an SPD beyond 1000 Vac. Allowing voltages beyond 1000 without a possible "listing" violates section 285.5 requiring a "listed" device.

As a working group member of UL 1449 and the IEEE PES Surge Protective Device (3.6) committees, there is no technical nor product-safety direction yet established by these standards committees. Therefore, I have even greater reluctance toward the NEC including voltages beyond 1000 Vac. Without a solid product-safety standard to address SPDs between 1000 and 2000 Vac, the NFPA should not change the 285.1

In reality, the ANSI C84 standard does not recognize any low-voltage electrical system beyond 600 volts. We do know that Wind Turbines do deliver a 690Y/400 V system - this is unique to these systems. Therefore, even stating "up to 1000 V" is more than what is covered in other standards.

The fact that the C84.1-2011 standard remains nebulous between 600 and 2400 volts should also cause the NFPA pause as well.

Keeping the maximum voltage at 1000 volts maintains code consistency with the change to up the low voltage range from 600 to 1000 volts.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

### Statement of Problem and Substantiation for Public Comment

ANSI/UL1449-2014 includes other "component assemblies" - these should be listed in this section because of confusion in the field over what is meant by "other component types".

<tbody>
<tr>
<td>Resolution:</td>
<td>The various types of surge-protective devices (SPD) are defined in Article 100. Type 4 is defined as a component assembly, which is not suitable for field installation. If the SPD is not listed but is a recognized component, then it is to only be installed by a manufacturer or as a replacement in a listed product.</td>
</tr>
</tbody>
</table>
Paralleled Installations.

AC and DC Conductors shall be permitted to be run in parallel in accordance with the provisions of 310.10(H). The requirement to run all circuit conductors within the same raceway, auxiliary gutter, cable tray, trench, cable, or cord shall apply separately to each portion of the paralleled installation, and the equipment grounding conductors shall comply with the provisions of 250.122. Parallel runs in cable tray shall comply with the provisions of 392.20(C).

Exception: DC Conductors shall be permitted to be arranged as isolated polarity, neutral, and grounded conductor installations and the raceways, auxiliary gutter, cable tray, trench, cable, or cord shall be installed in close proximity.

Exception: AC Conductors installed in nonmetallic raceways run underground shall be permitted to be arranged as isolated phase, neutral, and grounded conductor installations. The raceways shall be installed in close proximity, and the isolated phase, neutral, and grounded conductors shall comply with the provisions of 300.20(B).

Statement of Problem and Substantiation for Public Comment

the panel is right in saying induction is not an issue with DC, however without a reference to allow isolated parallel polarity one can think it is not allowed, 300.3 (B) applies to AC and DC systems. and if induction is not an issue this type of install should also be allowed for DC.

Submitter Information Verification

Submitter Full Name: ALFIO TORRISI
Organization: master
Street Address: 
City: 
State: 
Zip: 
Submittal Date: Fri Sep 04 15:43:58 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: Inserting the phrase “AC and DC” at the beginning paragraph in (B)(1) is unnecessary since the requirement in 300.3(B)(1) for compliance with 310.10(H) already accomplishes the submitter’s request since 310.10(H) clearly covers both ac and dc parallel conductor installations. The existing Exception in 300.3(B)(1) applies to ac conductors installed in nonmetallic raceways in underground installations only. Public Input 3271 limited the installation to nonmetallic conduit in underground installations only. The proposed text in Comment 555 permits dc conductors of any type to be installed as isolated polarities in any installation with any type wiring method, cord, or cable, above ground or below ground, without consideration of any dc source, even those that may be interrupted at a rate of 10 Hz to 200 Hz (pulsating dc). The unlimited installations of dc conductors without regard to the source cannot be done without technical substantiation of the effects on insulation and conductor resistance for power sources with pulsating dc.
300.4 Protection Against Physical Damage.

Where subject to physical damage, conductors, raceways, and cables shall be protected.

(A) Cables and Raceways Through Wood Members.

(1) Bored Holes.

In both exposed and concealed locations, where a cable- or raceway-type wiring method is installed through bored holes in joists, rafters, or wood members, holes shall be bored so that the edge of the hole is not less than 32 mm (1 \(\frac{1}{4}\) in.) from the nearest edge of the wood member. Where this distance cannot be maintained, the cable or raceway shall be protected from penetration by screws or nails by a listed and marked steel plate(s) or bushing(s) at least 1.6 mm (\(\frac{1}{16}\) in.) thick and of appropriate length and width installed to cover the area of the wiring.

Exception No. 1: Steel plates shall not be required to protect rigid metal conduit, intermediate metal conduit, rigid nonmetallic conduit, or electrical metallic tubing.

Exception No. 2: A listed and marked steel plate less than 1.6 mm (\(\frac{1}{16}\) in.) thick that provides equal or better protection against nail or screw penetration shall be permitted.

Informational Note: ANSI/UL 2239 defines requirements for listed steel bushings.

(2) Notches in Wood.

Where there is no objection because of weakening the building structure, in both exposed and concealed locations, cables or raceways shall be permitted to be laid in notches in wood studs, joists, rafters, or other wood members where the cable or raceway at those points is protected against nails or screws by a listed and marked steel plate at least 1.6 mm (\(\frac{1}{16}\) in.) thick and of appropriate length and width, installed to cover the area of the wiring. The steel plate shall be installed before the building finish is applied.

Exception No. 1: Steel plates shall not be required to protect rigid metal conduit, intermediate metal conduit, rigid nonmetallic conduit, or electrical metallic tubing.

Exception No. 2: A listed and marked steel plate less than 1.6 mm (\(\frac{1}{16}\) in.) thick that provides equal or better protection against nail or screw penetration shall be permitted.

(B) Nonmetallic-Sheathed Cables and Electrical Nonmetallic Tubing Through Metal Framing Members.

(1) Nonmetallic-Sheathed Cable.

In both exposed and concealed locations where nonmetallic-sheathed cables pass through either factory- or field-punched, cut, or drilled slots or holes in metal members, the cable shall be protected by listed bushings or listed grommets covering all metal edges that are securely fastened in the opening prior to installation of the cable.

Exception: A listed and marked steel plate less than 1.6 mm (\(\frac{1}{16}\) in.) thick that provides equal or better protection against nail or screw penetration shall be permitted.

(2) Nonmetallic-Sheathed Cable and Electrical Nonmetallic Tubing.

Where nails or screws are likely to penetrate nonmetallic-sheathed cable or electrical nonmetallic tubing, a listed and marked steel sleeve, steel plate, or steel clip not less than 1.6 mm (\(\frac{1}{16}\) in.) in thickness shall be used to protect the cable or tubing. Exception: A listed and marked steel plate less than 1.6 mm (\(\frac{1}{16}\) in.) thick that provides equal or better protection against nail or screw penetration shall be permitted.

(C) Cables Through Spaces Behind Panels Designed to Allow Access.

Cables or raceway-type wiring methods, installed behind panels designed to allow access, shall be supported according to their applicable articles.
Cables and Raceways Parallel to Framing Members and Furring Strips.

In both exposed and concealed locations, where a cable- or raceway-type wiring method is installed parallel to framing members, such as joists, rafters, or studs, or is installed parallel to furring strips, the cable or raceway shall be installed and supported so that the nearest outside surface of the cable or raceway is not less than 32 mm (1 ⅛ in.) from the nearest edge of the framing member or furring strips where nails or screws are likely to penetrate. Where this distance cannot be maintained, the cable or raceway shall be protected from penetration by nails or screws by a listed and marked steel plate, sleeve, or equivalent at least 1 6 mm (4/16 in.) thick.

Exception No. 1: Steel plates, sleeves, or the equivalent shall not be required to protect rigid metal conduit, intermediate metal conduit, rigid nonmetallic conduit, or electrical metallic tubing.

Exception No. 2: For concealed work in finished buildings, or finished panels for prefabricated buildings where such supporting is impracticable, it shall be permissible to fish the cables between access points. Exception No. 3: A listed and marked steel plate less than 1 6 mm (4/16 in.) thick that provides equal or better protection against nail or screw penetration shall be permitted.

Cables, Raceways, or Boxes Installed in or Under Roof Decking.

A cable, raceway, or box, installed in exposed or concealed locations under metal-corrugated sheet roof decking, shall be installed and supported so there is not less than 38 mm (1 ½ in.) measured from the lowest surface of the roof decking to the top of the cable, raceway, or box. A cable, raceway, or box shall not be installed in concealed locations in metal-corrugated, sheet deck- type roof.

Informational Note: Roof decking material is often repaired or replaced after the initial raceway or cabling and roofing installation and may be penetrated by the screws or other mechanical devices designed to provide "hold down" strength of the waterproof membrane or roof insulating material.

Exception: Rigid metal conduit and intermediate metal conduit shall not be required to comply with 300.4(E).

Cables and Raceways Installed in Shallow Grooves.

Cable- or raceway-type wiring methods installed in a groove, to be covered by wallboard, siding, paneling, carpeting, or similar finish, shall be protected by 1 6 mm (4/16 in.) thick a listed and marked steel plate, sleeve, or equivalent or by not less than 32 mm (1 ⅛ in.) free space for the full length of the groove in which the cable or raceway is installed.

Exception No. 1: Steel plates, sleeves, or the equivalent shall not be required to protect rigid metal conduit, intermediate metal conduit, rigid nonmetallic conduit, or electrical metallic tubing. Exception No. 2: A listed and marked steel plate less than 1 6 mm (4/16 in.) thick that provides equal or better protection against nail or screw penetration shall be permitted.

Insulated Fittings.

Where raceways contain 4 AWG or larger insulated circuit conductors, and these conductors enter a cabinet, box, an enclosure, or a raceway, the conductors shall be protected by an identified fitting providing a smoothly rounded insulating surface, unless the conductors are separated from the fitting or raceway by identified insulating material that is securely fastened in place.

Exception: Where threaded hubs or bosses that are an integral part of a cabinet, box, enclosure, or raceway provide a smoothly rounded or flared entry for conductors.

Conduit bushings constructed wholly of insulating material shall not be used to secure a fitting or raceway. The insulating fitting or insulating material shall have a temperature rating not less than the insulation temperature rating of the installed conductors.

Structural Joints.

A listed expansion/deflection fitting or other approved means shall be used where a raceway crosses a structural joint intended for expansion, contraction or deflection, used in buildings, bridges, parking garages, or other structures.

Statement of Problem and Substantiation for Public Comment

The Panel 3 response to PI 1592 noted a lack of evaluation of protector plates from several manufacturers. This has now been addressed. Video is accessible at the link which demonstrates that several NEC-compliant protector plates from different manufacturers do not stop penetration from self-drilling drywall screws. https://erico.box.com/s/0uvbl0bqapv2j5jh3zaqgyq6ix7r

If the NEC does not require listing of all protector plates, then there is a safety issue that is not being addressed. Self-drilling drywall screws easily penetrate 1/16" thick protector plates made from low carbon steel (like they all are). Please watch the linked video which demonstrates that NEC-compliant protector plates from several manufacturers clearly exhibit poor resistance to penetration. As it stands today, STP2239 and CANENA withdrew the proposal which had already been accepted to define testing requirements for protector plates, likely due to pressure from specific manufacturers. Without a listing requirement in the NEC, there is no motivation for STP2239 to follow through with defining evaluation requirements for all protector plates.

Note that in the video demonstration there is no drywall. Without drywall providing support to the drywall screw, it requires the installer to use less force to prevent the screw from skipping off the protector plate. Therefore, if drywall was present, the screws would penetrate in even less time.

<tr>
<td><strong>Resolution:</strong> Section 5.2.4 in UL 2239 only requires that a protector plate or protector bushing provide sufficient resistance to penetration to create ready awareness of the presence of concealed wires and cables through a framing member and a degree of protection from driven screws and nails. Section 5.2.5 requires a protector plate to be made of steel that is a minimum of 1/16 inch thick and must be provided with corrosion protection. Accepting the proposed new text would exclude the use of FHA straps and similar protection used throughout the building industry without technical substantiation for protection of plumbing, electrical, and other building applications where protection from penetration is necessary.</td>
</tr>
</tbody>
</table>
Where subject to physical damage, conductors, raceways, and cables shall be protected.

Informational Note: Physical damage is not expected to occur to concealed wiring methods during normal building operation. Minor damage to a raceway, cable armor or cable insulation does not necessarily violate the integrity of either the contained conductors or the conductors’ insulation.

Statement of Problem and Substantiation for Public Comment

This informational note provides guidance regarding wiring integrity and physical damage. There are many places in the NEC that refer to "physical damage", and concealment behind walls in accordance with installation requirements in the NEC protects wiring from physical damage during normal building operation. Since we have no definition of "physical damage" in the NEC and there have been instances of inspectors rejecting installations with minor scrapes on wiring methods, the second sentence provides guidance for those cases.

The panel stated that "The addition of this Informational Note does not provide any valuable information to the user to determine violation of integrity of the conductors or conductor insulation where damage to the raceway has occurred." This informational note is not intended to provide such information. It is intended to indicate to users of the code that minor blemishes on a wiring method do not necessarily mean that the wiring method must be replaced or that it is incapable of functioning. To clarify that, the word "Visible" was replaced with "Minor" as the first word in the second sentence.

Public Input No. 4306-NFPA 70-2014 [Section No. 300.4 [Excluding any Sub-Sections]]

Submitter Full Name: Christel Hunter
Organization: General Cable
Street Address:
City:
State:
Zip:
Submittal Date: Wed Sep 23 05:57:30 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Statement: The informational note provides guidance to an electrical inspector that minor (superficial) damage to the jacket of a cable is not an issue. The first sentence of the proposed informational note is unnecessary since it states the obvious that physical damage doesn't just occur from normal building operation.
(B) Nonmetallic-Sheathed Cables and Electrical Nonmetallic Tubing Through Metal Framing Members.

(1) Nonmetallic-Sheathed Cable.

In both exposed and concealed locations where nonmetallic-sheathed cables pass through either factory- or field-punched, cut, or drilled slots or holes in metal members, the cable shall be protected by listed bushings or listed grommets covering all metal edges that are securely fastened in the opening prior to installation of the cable.

(2) Nonmetallic-Sheathed Cable, Cables, and Electrical Nonmetallic Tubing.

Where nails or screws are likely to penetrate nonmetallic-sheathed cable or electrical nonmetallic tubing, a steel sleeve, steel plate, or steel clip not less than 1.6 mm (\(1\frac{1}{16}\) in.) in thickness shall be used to protect the cable or tubing.

Exception: A listed and marked steel plate less than 1.6 mm (\(1\frac{1}{16}\) in.) thick that provides equal or better protection against nail or screw penetration shall be permitted.

Statement of Problem and Substantiation for Public Comment

What generated the original input was the very common use of metallic 'shallow studs' (which are considerably narrower than a standard 3.5” stud) these also have factory field punched holes but do not offer the same protection as a standard 3.5” metal stud. This same code article requires protection for MC cable when running parallel where 11/4” is not met. The same possible short circuit would occur when running horizontal in shallow studs because maintaining 11/4” is not possible. I entered this same proposal in 2014 and the panel stated that it was already required in 300.4. Please look closely and reconsider for at least consistency or remove the protection requirement when running parallel

Committee Statement

Committee Action: Rejected
Resolution: Both Type MC and AC cables have requirements in 330.12(1) and 320.12(1) that preclude installing these cables in locations subject to physical damage. The proposed text in both the Public Input and the Public Comment would be too restrictive since it would require any cables installed in metal framing members to comply with this application. For example, Type MI cable would not require the same protection. As stated in the Panel Statement for Public Input 3789, there has been no indication or technical substantiation that a problem exists and none has been provided by the Public Comment.
Minimum Cover Requirements.
Direct-buried cable or conduit or other raceways shall be installed to meet the minimum cover requirements of Table 300.5.

A lesser depth shall be permitted where specified in the installation instructions of a listed low voltage lighting system.

Notes:
1. Cover is defined as the shortest distance in millimeters (inches) measured between a point on the top surface of any direct-buried conductor, cable, conduit, or other raceway and the top surface of finished grade, concrete, or similar cover.
2. Raceways approved for burial only where concrete encased shall require concrete envelope not less than 50 mm (2 in.) thick.
3. Lesser depths shall be permitted where cables and conductors rise for terminations or splices or where access is otherwise required.
4. Where one of the wiring method types listed in Columns 1 through 3 is used for one of the circuit types in Columns 4 and 5, the shallowest depth of burial shall be permitted.
5. Where solid rock prevents compliance with the cover depths specified in this table, the wiring shall be installed in a metal raceway, or a nonmetallic raceway permitted for direct burial. The raceways shall be covered by a minimum of 50 mm (2 in.) of
Concrete extending down to rock.

Statement of Problem and Substantiation for Public Comment

Webster's Definition of a "parking lot": an area, usually divided into individual spaces, intended for parking motor vehicles. This additional language trying to declare that it is still a parking lot was rejected with the panel statement declaring that 24" are required in some cases but not all depending on the construction of the slab. I reach out to the inspector members and try and explain to a contractor that Yes we are under a building but 24" is required where on the 2nd level of parking there is only 6" of concrete and it is allowed to place conduits in it. Adding this language or an informational note would allow for consistency. Is it under a building or is it under a parking lot??? thank you for the consideration

Public Input No. 2923-NFPA 70-2014 [Section No. 300.5(A)]

Submitter Information Verification

Submitter Full Name: James Dorsey
Organization: Douglas County
Street Address:  
City: 
State: 
Zip: 
Submittal Date: Fri Sep 25 10:57:58 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The Panel reaffirms the Public Input Statement as follows: “Adding an exclusion for under a building where the lower level is not a parking lot is already in Table 300.5 where the burial depth would be zero inches for most building at grade level without a parking area at grade level and 24 inches under a building with parking at grade level due to the flexing of the floor when a vehicle is driving over that area of the floor. There may be mitigating circumstances where the floor at grade is constructed using pre-stress cables or other construction methods to ensure the floor would not flex where vehicles are driving over it.” Building and slab on grade construction, such as post tension slabs, and similar architectural designs can certainly mitigate or eliminate the problems with slabs and underground raceway flexing. The structural engineer and plan review engineers can and should make the determination on whether a design will permit electrical raceways to be installed at lesser depths that shown in the Table.
Public Comment No. 1219-NFPA 70-2015 [Section No. 300.5(D)(3)]

(3) Service Conductors.

Underground service conductors and feeders, that are not encased in concrete and that are buried 450 mm (18 in.) or more below grade shall have their location identified by a warning ribbon that is placed in the trench at least 300 mm (12 in.) above the underground installation.

Statement of Problem and Substantiation for Public Comment

Please reconsider the action taken at the public input stage. This is a potential safety issue for electrical workers.

Note that the public comment restricts this to feeders from the original public input.

The NEC Handbook states that this ribbon is not required for feeders because, unlike service conductors, these have short circuit and overload protection. Throughout the NEC the code goes to great lengths to provide physical protection of electrical conductors so it's difficult to find logic with the reason given in the NEC Handbook. A warning ribbon installed at the proper height above the feeders provides a higher degree of safety for electrical workers. It also can be a great value for so little cost considering repairs and down time in the event these conductors are hit. It is a sensible precaution in preventing ground faults or short circuits.

Submitter Information Verification

Submitter Full Name: Marcelo Hirschler
Organization: GBH International
Street Address:
City:
State:
Zip:
Submittal Date: Thu Sep 24 13:39:35 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: This Public Comment did not provide any technical substantiation for adding a warning ribbon for all underground feeders. Feeders, just like branch circuits, can be 15 amperes and higher with both feeders and branch circuits protected against short circuits and ground faults with appropriate overcurrent protective devices, unlike service conductors that are only protected at their load side against overload. The original purpose of the ribbon installation for directly buried service conductors has not changed since the text was inserted into the 1999 NEC. Cable and conductor location companies and devices are readily available to help determine where there are underground directly buried conductors. Section 130.9 of NFPA 70E further states “before excavation starts where there exists a reasonable possibility of contacting electrical lines or equipment, the employer shall take the necessary steps to contact the appropriate owners or authorities to identify and mark the location of the electrical lines or equipment. When it has been determined that a reasonable possibility of contacting electrical lines or equipment exists, appropriate safe work practices and PPE shall be used during the excavation.”
Public Comment No. 1392-NFPA 70-2015 [Section No. 300.5(D)(3)]

(3) Service Conductors.
Underground service conductors and feeders, that are not encased in concrete and that are buried 450 mm (18 in.) or more below grade shall have their location identified by a warning ribbon that is placed in the trench at least 300 mm (12 in.) above the underground installation.

Statement of Problem and Substantiation for Public Comment

This language would provide a very low cost to an installation that could save major costs to equipment that may be damaged by digging into underground feeders. This minimum installation provides a greater degree of safety to property and electrical equipment.

Statement of Problem and Substantiation for Public Comment

As an electrical inspector on a military base, we constantly see underground installations damaged by new construction cutting into existing raceways/cables. We almost NEVER see that damage occur when the ribbon is installed, only on existing installations where the ribbon is not required. Frankly, the cost of the ribbon is negligible and the benefit of not damaging the existing circuits would far outweigh the minimal cost. We have a LOT of raceways underground around here. Digging is almost always an adventure, even though we "locate" the existing stuff before we start. That science is helpful, but by no means absolute. I'd like to see the practice of installing the ribbon applied to EVERY underground installation (18 inches and deeper), including branch circuits, but for now, I'm suggesting that we add feeders to the requirement.

When it has been determined that a reasonable possibility of contacting electrical lines or equipment exists, appropriate safe work practices and PPE shall be used during the excavation."
(4) Enclosure or Raceway Damage.
Where the enclosure or raceway is subject to physical damage, the conductors shall be installed in steel (not aluminum) electrical metallic tubing, rigid metal conduit, intermediate metal conduit, RTRC-XW, Schedule 80 PVC conduit, or equivalent.

Statement of Problem and Substantiation for Public Comment

Aluminum EMT has a much lower crush/bend rating than steel EMT, and therefore should not be considered as a viable method of protection of conductors against damage.

Related Item
First Revision No. 606-NFPA 70-2015 [Section No. 300.5(D)(4)]

Submittal Date: Tue Sep 22 16:49:40 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: Section 358.12(1) does not differentiate between steel EMT and aluminum EMT as to the limitation and restriction of severe physical damage. Both types of EMT will withstand a certain amount of physical damage but not severe physical damage. Care must be taken with the use of aluminum EMT in underground applications. Compliance with 300.6 for extra corrosion protection may be necessary in certain soil conditions.
Public Comment No. 99-NFPA 70-2015 [Section No. 300.7(B)]

(B) Expansion Fittings.
Raceways shall be provided with expansion fittings or expansion/deflection fittings where necessary to compensate for thermal expansion and contraction.

Informational Note: Table 352.44 and Table 355.44 provide the expansion information for polyvinyl chloride (PVC) and for reinforced thermosetting resin conduit (RTRC), respectively. A nominal number for steel conduit can be determined by multiplying the expansion length in Table 352.44 by 0.20. The coefficient of expansion for steel electrical metallic tubing, intermediate metal conduit, and rigid metal conduit is $1.170 \times 10^{-5}$ (0.0000117 mm per mm of conduit for each °C in temperature change) [$0.650 \times 10^{-5}$ (0.0000065 in. per inch of conduit for each °F in temperature change)].

A nominal number for aluminum conduit and aluminum electrical metallic tubing can be determined by multiplying the expansion length in Table 352.44 by 0.40. The coefficient of expansion for aluminum electrical metallic tubing and aluminum rigid metal conduit is $2.34 \times 10^{-5}$ (0.0000234 mm per mm of conduit for each °C in temperature change) [1.30 $\times 10^{-5}$ (0.000013 in. per inch of conduit for each °F in temperature change)].

Statement of Problem and Substantiation for Public Comment

Reconsider Resolved Public Input #1899 and revise 300.7(B). A standard expansion fitting works when the raceways is installed a straight axial alignment whereas the expansion/deflection fitting accommodates for the raceway's thermal expansion or contraction when the raceways are off-set or misaligned. The proposed language makes it clear to inspectors, designers and contractors that expansion/deflection fittings are acceptable to be used with a raceways to address thermal expansion and contraction.

Resolution: SR-602-NFPA 70-2015
Statement: The revised text makes it clear to inspectors, designers, and contractors that expansion-deflection and deflection fittings are acceptable to be used with raceways to address thermal expansion, deflection, and contraction. Revising the text also requires a revision of the title to this subsection.
Public Comment No. 1641-NFPA 70-2015 [Section No. 300.9]

300.9 Raceways in Wet Locations Abovegrade.
Where raceways are installed in wet locations abovegrade, the interior of these raceways shall be considered to be a wet location unless all fittings and enclosures are listed watertight. Insulated conductors and cables installed in raceways in wet locations abovegrade without all fittings and enclosures listed watertight shall comply with 310.10(C).

Statement of Problem and Substantiation for Public Comment

I submitted PI 627 and PI 628 and both PIs were resolved. I read the committee statement and wanted to submit a public comment however the system will not let me relate this public comment to either of my PIs. Hopefully this will work and CMP 3 will be able to respond to my public comment. This comment applies to 300.9 and 300.38.

When I submitted PI 627 and PI 628 I used the term "raintight" and that was an error. I should have used the term "watertight".

Sections 300.9 and 300.38 as currently written do not recognize material listed as "watertight". Installers are required to use fittings and enclosures listed for use in wet locations when installing raceway systems on the exterior of a building. The UL White Book states "For equipment designated watertight the equipment is so constructed that water does not enter the enclosure when subjected to a stream of water." The definition in Article 100 for watertight is "constructed so that moisture will not enter the enclosure under specified test conditions." The NEC must recognize that a listed product will perform to the standard for which it was tested. Throughout the NEC are listing requirements and AHJs put their faith in qualified electrical testing laboratories that the listed products will perform as tested. The interior of raceways installed in wet locations above grade utilizing listed watertight fittings and enclosures cannot be considered a wet location.

Related Item

Public Input No. 640-NFPA 70-2014 [Section No. 300.9]

Submitter Information Verification

Submitter Full Name: ROBERT JONES
Organization: IEC Texas Gulf Coast

Committee Statement

Committee Action: Rejected
Resolution: The use of "raintight" and "watertight" is really not the issue here, however, the marking on a package of fittings for raintight, wet location, or the equivalent on the carton indicates suitability for use where directly exposed to rain. The issue here is that raceways installed above grade may have water entry from outside or may have a difference of temperature, either during the day or night, such that the humidity in the area may cause moisture to develop on the conductors and within the raceway. Section 312.2 covering enclosures that states as follows: "In damp or wet locations, surface-type enclosures within the scope of this article shall be placed or equipped so as to prevent moisture or water from entering and accumulating within the cabinet or cutout box, and shall be mounted so there is at least 6-mm (1/4-in.) airspace between the enclosure and the wall or other supporting surface. Enclosures installed in wet locations shall be weatherproof. For enclosures in wet locations, raceways or cables entering above the level of uninsulated live parts shall use fittings listed for wet locations.; and 314.15 for boxes in damp or wet locations that states the following: "In damp or wet locations, boxes, conduit bodies, and fittings shall be placed or equipped so as to prevent moisture from entering or accumulating within the box, conduit body, or fitting. Boxes, conduit bodies, and fittings installed in wet locations shall be listed for use in wet locations. Approved drainage openings not larger than 6 mm (1/4 in.) shall be permitted to be installed in the field in boxes or conduit bodies listed for use in damp or wet locations. For installation of listed drain fittings, larger openings are permitted to be installed in the field in accordance with manufacturer’s instructions." The common application within each one of the previous examples in the existing NEC illustrates that fittings, enclosures, and raceways may or will have water entry from external sources or internal sources, such as condensation; hence, the reason 300.9 requires compliance with 310.10(C) for a wet location. Section 8.7.1 of UL 514B provides test results for testing fittings designed for use in wet locations with the following result: "As a result of the test, no amount of water greater than 0.1 ml or 0.1 g shall enter the fitting."
300.11 Securing and Supporting.

(A) Secured in Place.

Raceways, cable assemblies, boxes, cabinets, and fittings shall be securely fastened in place.

(B) Wiring Systems Installed Above Suspended Ceilings.

Support wires that do not provide secure support shall not be permitted as the sole support. Support wires and associated fittings that provide secure support and that are installed in addition to the ceiling grid support wires shall be permitted as the sole support. Where independent support wires are used, they shall be secured at both ends. Cables and raceways shall not be supported by ceiling grids.

(1) Fire-Rated Assemblies.

Wiring located within the cavity of a fire-rated floor-ceiling or roof-ceiling assembly shall not be secured to, or supported by, the ceiling assembly, including the ceiling support wires. An independent means of secure support shall be provided and shall be permitted to be attached to the assembly. Where independent support wires are used, they shall be distinguishable by color, tagging, or other effective means from those that are part of the fire-rated design.

Exception: The ceiling support system shall be permitted to support wiring and equipment that have been tested as part of the fire-rated assembly.

Informational Note: One method of determining fire rating is testing in accordance with ANSI/ASTM E119-2014, Method for Fire Tests of Building Construction and Materials.

(2) Non–Fire-Rated Assemblies.

Wiring located within the cavity of a non–fire-rated floor-ceiling or roof-ceiling assembly shall not be secured to, or supported by, the ceiling assembly, including the ceiling support wires. An independent means of secure support shall be provided and shall be permitted to be attached to the assembly. Where independent support wires are used, they shall be distinguishable by color, tagging, or other effective means.

Exception: The ceiling support system shall be permitted to support branch-circuit wiring and associated equipment where installed in accordance with the ceiling system manufacturer’s instructions.

(C) Raceways Used as Means of Support.

Raceways shall be used only as a means of support for other raceways, cables, or nonelectrical equipment under any of the following conditions:

(1) Where the raceway or means of support is identified as a means of support

(2) Where the raceway contains power supply conductors for electrically controlled equipment and is used to support Class 2 circuit conductors or cables that are solely for the purpose of connection to the equipment control circuits

(3) Where the raceway is used to support boxes or conduit bodies in accordance with 314.23 or to support luminaires in accordance with 410.36(E)

(D) Cables Not Used as Means of Support.

Cable wiring methods shall not be used as a means of support for other cables, raceways, or nonelectrical equipment.

(E) Metallic Means of Support Above Egress

Metallic means of support for flexible conduit and conductors shall be used in spaces above egress, which includes doorways, hallways, stairways, corridors, passageways, lobbies, landings, and equivalent spaces.

Informational note: Nonmetallic supports exhibit significant weakening and failure during fires which can affect the safety of occupants and emergency personnel entering and exiting buildings due to entanglement in fallen cable.

Statement of Problem and Substantiation for Public Comment

Emergency responders and building occupant safety is at risk during building fires because people can become entangled and trapped in cabling which has fallen out of molten or failing plastic supports/raceway. Even if people can free themselves from fallen cabling, this takes time which is otherwise needed to exit the building or fulfill the objectives of emergency personnel. The frequency of emergency responders becoming trapped in fallen cabling has become so common that firefighters have created and publicly distributed training videos on how to escape in these situations (http://www.fireengineering.com/topics/m/video/36926837/the-quick-release-method.htm?q=cable+entanglement) [1]. Additionally, the Greater Tucson Fire Foundation raised financial support in 2011 to purchase cable cutters for hundreds of Tucson, Arizona firefighters so that they are equipped to deal with cable entanglement [2].

The ideal scope of this requirement should include all wiring methods which are susceptible to falling during a fire. This includes insulated conductors, flexible metal conduit, and nonmetallic raceways with plastic supports. It should include power conductors, signaling conductors, fire alarm cables, and communications circuits. Although CMP 3 can only address a portion of the relevant scope,
I urge you to address what you can within the scope of 300.11 by accepting the intent of this proposal.

Since CMP 3 review of Public Input 4649 in January 2015, BS 7671 (UK Wiring Regulations) was published with Amendment 3 which requires metal supports for cables installed in escape routes [3, 4] and went into effect on July 1, 2015. This requirement is no longer limited only to fire alarm systems, but now includes all wiring methods.

**Committee Statement**

Committee Action: Rejected but held

Resolution: This should be addressed as a global issue within the NEC since it will affect many different articles throughout the NEC, such as many of the raceway and cable requirements in Chapter 3, Chapter 7, and Chapter 8 so it can only be dealt with initially by the NEC Correlating Committee. Panel 3 requests that the NEC Correlating Committee appoint a task group to address this issue before the next NEC cycle and also refer this to the Fire Protection Research Foundation for further research.
Fire-Rated Assemblies.

Wiring located within the cavity of a fire-rated floor-ceiling or roof-ceiling assembly shall not be secured to, or supported by, the ceiling assembly, including the ceiling support wires. An independent means of secure support shall be provided and shall be permitted to be attached to the assembly. Where independent support wires are used, they shall be distinguishable by color, tagging, or other effective means from those that are part of the fire-rated design.

Exception: The ceiling support system shall be permitted to support wiring and equipment that have been tested as part of the fire-rated assembly.

Statement: The ANSI/ASTM E119 has been changed from 2014 to 2015.
### 300.12 Mechanical Continuity — Raceways and Cables.

**A** Raceways and Cables. Raceways, cable armors, and cable sheaths shall be continuous between cabinets, boxes, fittings, or other enclosures or outlets.

*Exception No. 1:* Short sections of raceways used to provide support or protection of cable assemblies from physical damage shall not be required to be mechanically continuous.

*Exception No. 2:* Raceways and cables installed into the bottom of open bottom equipment, such as switchboards, motor control centers, and floor or pad-mounted transformers, shall not be required to be mechanically secured to the equipment.

**B** Reducing Washers. Metal reducing washers are permitted to be used with metal enclosures having a minimum thickness of 0.053 in. for non-service conductors only. Nonconductive coatings (such as paint, lacquer, and enamel) on metallic enclosures shall be removed from contact surfaces to ensure good electrical continuity as required by 250.12. Reducing washers are permitted to be installed in enclosures provided with concentric or eccentric knockouts, only after all of the concentric and eccentric rings have been removed.

*Exception:* Those enclosures containing concentric and eccentric knockouts that have been certified for bonding purposes shall be permitted to be used with reducing washers without all knockouts being removed.

### Statement of Problem and Substantiation for Public Comment

Reducing washers are commonly used in electrical installations and their installation should be covered in the NEC. At the present time the limited installation rules are in the UL White book under Outlet Bushings and Fittings (QCRV). This rule should be located here in Article 300 as the use of reducing washers is common to every cable and conduit wiring method that is connected to an enclosure as covered throughout the remainder of Chapter 3. Other articles such as Article 250 deal with the installation of reducing washers in a limited way.

The general requirement should be here in Article 300.

</tbody>
</table>
(A) Spacing Intervals — Maximum.

Conductors in vertical raceways shall be supported if the vertical rise exceeds the values in Table 300.19(A). At least one support method shall be provided for each conductor or cable assembly at the top of the vertical raceway or as close to the top as practical. Intermediate supports shall be provided as necessary to limit supported conductor lengths to not greater than those values specified in Table 300.19(A).

Exception: Steel wire armor cable shall be supported at the top of the riser with a cable support that clamps the steel wire armor. A safety device shall be permitted at the lower end of the riser to hold the cable in the event there is slippage of the cable in the wire-armored cable support. Additional wedge-type supports shall be permitted to relieve the strain on the equipment terminals caused by expansion of the cable under load.

Statement of Problem and Substantiation for Public Comment

A cable assembly is multiple conductors grouped together (usually by plexing) without an overall covering. Deleting "cable assembly" from the revised language ensures that each individual conductor is supported at the top of a vertical raceway, which can be accomplished by gland type fittings or other identified means of support.

Committee Statement

Committee Action: Accepted
Resolution: SR-604-NFPA 70-2015
Statement: Deleting cable assembly ensures that each individual conductor is supported at the top of a vertical raceway.
Public Comment No. 580-NFPA 70-2015 [Section No. 300.20(B)]

(B) Individual Conductors.

Where a single conductor carrying alternating current passes through metal with magnetic properties, the inductive effect shall be minimized by (1) cutting slots in the metal between the individual holes through which the individual conductors pass or (2) passing all the conductors in the circuit through an insulating wall sufficiently large for all of the conductors of the circuit.

Exception: In the case of circuits supplying vacuum or electric-discharge lighting systems, constant current regulator outputs used for airfield lighting series circuits, or signs or X-ray apparatus, the currents carried by the conductors are so small that the inductive heating effect can be ignored where these conductors are placed in metal enclosures or pass through metal.

Informational Note: Because aluminum is not a magnetic metal, there will be no heating due to hysteresis; however, induced currents will be present. They will not be of sufficient magnitude to require grouping of conductors or special treatment in passing conductors through aluminum wall sections.

Statement of Problem and Substantiation for Public Comment

The modification to the exception is necessary due to the way the series circuit conductors are routed through the light bases on the airfield.

A typical series circuit installation will have one leg of the circuit enter the galvanized steel light base on one side (let's say at 0 degrees), this conductor will connect to the isolation transformer. The other leg of the isolation transformer will connect to another conductor. This second conductor will exit the galvanized steel light base on the opposite side of the light base (at 180 degrees). The primary conductor enters and exits the galvanized steel enclosure (light base) through separate/distinct openings. No slots are cut between the openings. No effort or attempt is made to address inductive heating.

Submittal Date: Wed Sep 09 11:06:50 EDT 2015

Committee Statement

Committee Action: Rejected

Resolution: Public Input 2739, as referenced in the related items, doesn't appear to have been accepted as a First Revision. Article 392 applies to cable tray systems and this would seem to be more adequately addressed in 310.10(F), Exception No. 2 rather than in 392.10(D) as indicated in Related Comments for this Document at the bottom of the Public Comment 580. Article 300 contains general requirements for wiring methods. Specific wiring methods should be inserted in the appropriate Article in Chapter 3.
Public Comment No. 1788-NFPA 70-2015 [Section No. 300.22(B)]

(B) Ducts Specifically Fabricated for Environmental Air.

Equipment, devices, and the wiring methods specified in this section shall be permitted within such ducts only if necessary for the direct action upon, or sensing of, the contained air. Where equipment or devices are installed and illumination is necessary to facilitate maintenance and repair, enclosed gasketed-type luminaires shall be permitted.

Only wiring methods consisting of Type MI cable without an overall nonmetallic covering, Type MC cable employing a smooth or corrugated impervious metal sheath without an overall nonmetallic covering, electrical metallic tubing, intermediate metal conduit, or rigid metal conduit without an overall nonmetallic covering shall be installed in ducts specifically fabricated to transport environmental air. Flexible metal conduit shall be permitted, in lengths not to exceed 1.2 m (4 ft), to connect physically adjustable equipment and devices permitted to be in these fabricated ducts. The connectors used with flexible metal conduit shall effectively close any openings in the connection.

Exception: Wiring methods and cabling systems, listed for use in other spaces used for environmental air (plenums), shall be permitted to be installed in ducts specifically fabricated for environmental air-handling purposes under the following conditions:

1. The wiring methods or cabling systems shall be permitted only if necessary to connect to equipment or devices associated with the direct action upon or sensing of the contained air, and
2. The total length of such wiring methods or cabling systems shall not exceed 1.2 m (4 ft).

Statement of Problem and Substantiation for Public Comment

The Correlating Committee also directs that FR 3309 be referred to Panel 3 for comment, in regards to the limited distance in 300.22(B).

Committee Action: Rejected
Resolution: The Panel reviewed FR 3309 and proposes that Panel 12 consider revisions to 640.3 (B).
(3) Equipment.

Electrical equipment with a metal enclosure, or electrical equipment with a nonmetallic enclosure listed for use within an air-handling space and having low smoke and heat release properties, and associated wiring material suitable for the ambient temperature shall be permitted to be installed in such other space unless prohibited elsewhere in this Code.

Informational Note: One method to determine low smoke and heat release properties is that the equipment exhibits a maximum peak optical density of 0.50 or less, an average optical density of 0.15 or less, and a peak heat release rate of 100kW or less when tested in accordance with ANSI/UL 2043-2013, Fire Test for Heat and Visible Smoke Release for Discrete Products and Their Accessories Installed in Air-Handling Spaces.

Exception: Integral fan systems shall be permitted where specifically identified for use within an air-handling space.

Statement of Problem and Substantiation for Public Comment

Statement of Problem and Substantiation for Public Comment

I strongly support PI 2762 and request the CMP reconsider the PI.

Based upon my research, prior to 2004 and the first issue of FAA Advisory Circular 150/5340-30 there was no FAA prohibition to the practice of installing L-824 cable in free air within the airfield lighting vault. It appears the FAA requirements were revised to comply with the NEC at that time.

Historically many airfield lighting vaults were powered by 4,160 volt and 2,400 volt systems. Many of these installations were powered by distribution cable mounted on insulators attached to the airfield lighting vault walls. A cable tap protected by a fused cut-out powered the constant current regulator. Thankfully, this practice was also eliminated by the new AC in 2004.

The effort to bring harmony between the FAA Advisory Circulars and the NEC created an unexpected consequence.

The electrical characteristics of an airfield lighting series (current) circuit are significantly different than those of a conventional parallel (voltage) circuit we are all familiar with.

The practice of routing L-824 cable in free air (in locations accessible to qualified persons only) has been used safely and successfully throughout the industry to expedite troubleshooting and repair of airfield lighting circuits.

</tbody>
</table>

Statement of Problem and Substantiation for Public Comment

L-824 cable is designed to withstand a very harsh environment of direct earth burial and installation underground in raceways, manholes, hand holes and light bases. Please see photos attached to this Public Comment.

It is an extremely rare occurrence for the L-824 cable to fail in the controlled environment of an airfield lighting vault. In my 28 years of airfield lighting experience, I am aware of only two cable failures. Both of these L-824 cable failures were caused by the breakdown of the equipment to which the L-824 cable was connected.

Airfield lighting series circuits are current circuits; where a short circuit is considered as no load. There is virtually no arc-flash hazard involved on the output of a constant current regulator.

The constant current regulator output current is designed to stay fixed at the FAA mandated values of 6.6 amps (±0.1 A) or 20 amps (±0.3 A). The constant current regulator (CCR) output overcurrent protective device will not trip due to a change in series circuit resistance, shorts, or grounds in the airfield lighting circuit. The CCR recognizes a change in series circuit resistance, shorts, or grounds in the airfield lighting circuit as a change in load characteristics, and it adjusts the output voltage up or down to maintain the specified current. An open circuit is understood as an infinite increase in load, causing the CCR to trip on overvoltage.

I respectfully request the CMP re-examine PI-2762 and approve the use of exposed runs of FAA type L-824 cables in (airfield lighting vaults) locations accessible to qualified persons only.

</tr>
</tbody>
</table>

Statement of Problem and Substantiation for Public Comment

There are typically many thousands of feet of L-824 airfield lighting cable installed at airports; tens of thousands of feet at commercial airports. The requested exception is a very narrow application of the L-824 airfield lighting cable. The narrow limited application would be for use inside the airfield lighting vault. Access to the airfield lighting vault is limited to qualified persons. The free air cable length would typically be less than 5 or 6 feet and would nominally be supported by cable grips, ty-raps or other acceptable means.

I respectfully request the CMP re-examine PI-2762 and approve the use of exposed runs of FAA type L-824 cables in locations accessible to qualified persons only.

Statement of Problem and Substantiation for Public Comment

Allowing multiple L824 cables to be routed in raceways provides relatively quick access to cables in the electrical vault and with cables terminated with FAA L823 plugs and receptacles give the maintenance worker a number of options as to how to get a series circuit critical to the operation of a runway back in operation. Spare or alternate cable paths can quickly be patched in thus bypassing failed components or cable.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-624-NFPA 70-2015
Statement: This revision recognizes that these cables are often installed exposed within a restricted airport lighting vault to facilitate easy access for modifications and reconnections during emergency situations.
Public Comment No. 246-NFPA 70-2015 [Section No. 300.37]

300.37 Aboveground Wiring Methods.

Aboveground conductors shall be installed in rigid metal conduit, in intermediate metal conduit, in electrical metallic tubing, in RTRC and PVC conduit, in cable trays, in auxiliary gutters, as busways, as cablebus, in other identified raceways, or as exposed runs of metal-clad cable suitable for the use and purpose. In locations accessible to qualified persons only, exposed runs of Type MV cables, exposed runs of FAA L-824 cables, bare conductors, and bare busbars shall also be permitted. Busbars shall be permitted to be either copper or aluminum.

Informational Note: Federal Aviation Administration (FAA) Advisory Circulars (ACs) provide additional practices and methods for airport lighting.

Statement of Problem and Substantiation for Public Comment

Exposed runs of FAA L-824 cable is not specifically permitted in the NEC. Some authorities having jurisdiction do not see equivalence in permitting exposed runs of MV cables and exposed runs of L-824 cables in locations accessible only to qualified persons.

Substantiation:

Exposed portions of FAA L-824 Type C cable within airfield lighting vault buildings which have controlled access to qualified personnel only have been part of industry practice for decades. In particular, airfield lighting series circuits utilize series cutouts for maintenance and troubleshooting which may be wall mounted per the manufactures instructions. Wires connecting to the series cutouts are exposed when the series cutouts are wall mounted. FAA L-824 Type C cable is permitted and rated by the manufacturers for aerial use in addition to underground direct burial, raceways, and in ducts. Aerial use is exposed above ground use. FAA advisory circular 150/5345-7E and F permits FAA L-824 Type C cable to be used in buildings and with controlled access by authorized personnel only the exposed cable complies with Article 300.37.

Statement of Problem and Substantiation for Public Comment

Public Input No. 2762-NFPA 70-2014 (Section No. 300.37)

• Comments to Substantiation commentary from Carl Johnson – Avcon10/29/14

Section No. 300.37 discusses the application and protection of L824 cables that are used to power airfield lights. The system is set up such that Edison Power, which is voltage controlled is brought into a vault on the airfield. The Edison power goes through switchgear to transform to airfield application needs and then is transformed via a plurality of constant current regulators to deliver power to airfield circuits that are current controlled in series. The constant current regulator is used to control current at specified steps or intensities to control the brightness of the lights on the airfield depending on varying visibility conditions. Each constant current regulator typically controls the lighting for a designated geographic area on the airfield (ie, Taxiway A Edge Lights, Runway 18 Centerline Lights, Runway 27 Edge Lights, Runway 9 Threshold Lights, etc.).

The airfield vault houses the switchgear and constant current regulator units and is similar to an electrical substation. It is the key area and acts as the brain of the airfield lighting system. Therefore, it is very important that the equipment is maintained and serviced to the highest quality standards to support the effective lighting of an airfield, which is critical to aircraft and personal safety.

It is a very controlled area. Only authorized personnel are allowed in the airfield vault for monitoring or maintenance needs. Carl Johnson II discusses some of those needs in his post from 10/29/14. The point I want to highlight is the criticality of timeliness of completion of those tasks. If there are issues that need to be diagnosed and tested on an airfield, the vault, regulators and their fed circuits must be accessed quickly and resolutions employed right away to prevent an unsafe airport operation.

Section No. 300.37 addresses the safety of access to L824 cables throughout the airfield environment which is open to many contractors and construction personnel as they work on electrical systems. The protection of these cables in conduit and the other protection devices mentioned is critically important to safety as the ability to control personnel that come into interaction with such cables is more difficult to manage. However, access to and in the vault is more controlled and procedures are validated and audited. Further, the equipment in the vault must be readily accessible to authorized personnel to properly maintain and control with timely solutions in an effort to protect the safety of everyone in an airfield environment that uses airfield lighting to transport passengers via aircraft.

It is critically important that authorized personnel have readily available access to L824 cables and those cables should be permitted to be installed in exposed runs in the airfield lighting vault only.

Resolution: This Comment is not in conformance with 4.4.4.3(c) of the NFPA Rules and Regulations since Public Comments must include the proposed text of the Public Comment, including the wording to be added, revised (and how revised), or deleted. The changes must be indicated through the use of underlines for new text and strike through for deleted text.
Public Comment No. 374-NFPA 70-2015 [Section No. 310.15(A)(2)]

(2) Selection of Ampacity.
Where more than one ampacity applies for a given circuit length, the lowest value shall be used.

Exception: Where different ampacities apply to portions of a circuit because of temperature correction in accordance with 310.15(B)(3)(a), the higher ampacity shall be permitted to be used if the total portion(s) of the circuit with lower ampacity does not exceed the lesser of 3.0 m (10 ft) or 10 percent of the total circuit.

Informational Note: See 110.14(C) for conductor temperature limitations due to termination provisions.

Statement of Problem and Substantiation for Public Comment

Since the exception only applies to temperature correction, the exception should make this clear. Also 310.15(B)(3)(a) is proposed to exclude the exception.

Selection of Ampacity.

Where more than one ampacity applies for a given circuit length, the lowest value shall be used.

Exception: Where different ampacities apply to portions of a circuit because of conductor ampacity temperature correction in accordance with 310.15(B)(3)(a), the higher ampacity shall be permitted to be used if the total portion(s) of the circuit with lower ampacity does not exceed the lesser of 3.0 m (10 ft) or 10 percent of the total circuit.

Informational Note: See 110.14(C) for conductor temperature limitations due to termination provisions.

Statement of Problem and Substantiation for Public Comment

310.15(B)(3)(a) now prohibits the use of this exception, then the exception should state the condition that it applies.

Committee Statement

Committee Action: Rejected
Resolution: The change proposed by the comment in no longer applicable. See Panel action taken on SR1506.
(3) Adjustment Factors.

(a) More than Three Current-Carrying Conductors. Where the number of current-carrying conductors in a raceway or cable exceeds three, or where single conductors or multicconductor cables are installed without maintaining spacing for a continuous length longer than 600 mm (24 in.) and are not installed in raceways, the allowable ampacity of each conductor shall be reduced as shown in Table 310.15(B)(3)(a). Section 310.15(A)(2) exception shall not apply. Each current-carrying conductor of a paralleled set of conductors shall be counted as a current-carrying conductor.

Where conductors of different systems, as provided in 300.3, are installed in a common raceway or cable, the adjustment factors shown in Table 310.15(B)(3)(a) shall apply only to the number of power and lighting conductors (Articles 210, 215, 220, and 230).

Informational Note No. 1: See Annex B for adjustment factors for more than three current-carrying conductors in a raceway or cable with load diversity.

Informational Note No. 2: See 366.23 for adjustment factors for conductors and ampacity for bare copper and aluminum bars in auxiliary gutters and 376.22(B) for adjustment factors for conductors in metal wireways.

(1) Where conductors are installed in cable trays, the provisions of 392.80 shall apply.

(2) Adjustment factors shall not apply to conductors in raceways having a length not exceeding 600 mm (24 in.).

(3) Adjustment factors shall not apply to underground conductors entering or leaving an outdoor trench if those conductors have physical protection in the form of rigid metal conduit, intermediate metal conduit, rigid polyvinyl chloride conduit (PVC), or reinforced thermosetting resin conduit (RTRC) having a length not exceeding 3.05 m (10 ft), and if the number of conductors does not exceed four.

(4) Adjustment factors shall not apply to Type AC cable or to Type MC cable under the following conditions:

a. The cables do not have an overall outer jacket.

b. Each cable has not more than three current-carrying conductors.

c. The conductors are 12 AWG copper.

d. Not more than 20 current-carrying conductors are installed without maintaining spacing, are stacked, or are supported on "bridle rings."

Exception: A 60 percent adjustment factor shall be applied if the current-carrying conductors in these cables that are stacked or bundled longer than 600 mm (24 in.) without maintaining spacing exceeds 20.

(5) An adjustment factor of 60 percent shall be applied to Type AC cable or Type MC cable under the following conditions:

a. The cables do not have an overall outer jacket.

b. The number of current carrying conductors exceeds 20.

c. The cables are stacked or bundled longer that 600 mm (24 in.) without spacing being maintained.

1Number of conductors is the total number of conductors in the raceway or cable, including spare conductors. The count shall be adjusted in accordance with 310.15(B)(5) and (6). The count shall not include conductors that are connected to electrical components that cannot be simultaneously energized.

(b) Raceway Spacing. Spacing between raceways shall be maintained.

(c) Raceways and Cables Exposed to Sunlight on Rooftops. Where raceways or cables are exposed to direct sunlight on or above rooftops, raceways or cables shall be installed a minimum distance above the roof to the bottom of the raceway or cable of 23 mm (.7/8 - in.). Where the distance above the roof to the bottom of the raceway is less than 23 mm (.7/8 - in.), a temperature adder of 33°C (60°F) shall be added to the outdoor temperature to determine the applicable ambient temperature for application of the correction factors in Table 310.15(B)(2)(a) or Table 310.15(B)(2)(b).

Exception - Type XHHW-2 insulated conductors shall not be subject to this ampacity adjustment.

Informational Note: One source for the ambient temperatures in various locations is the ASHRAE Handbook — Fundamentals.

Statement of Problem and Substantiation for Public Comment

The adders in 310.15(B)(3)(c) are unnecessary. The Southern Nevada Chapter of IAEI sponsored an additional investigative experiment.
during the summer of 2015. The experimental data was gathered and analyzed by the University of Las Vegas, Nevada. The UNLV report was submitted to NFPA as supporting material. The conclusions of the study indicate the following:

- Maximum recorded ambient temperature in summer 2015: 44°C
- Conductor rated temperature: 90°C
- Allowable ampacity of installed conductors with adders: 15.6 A.
- Allowable ampacity of installed conductors without adders: 20.88 A.
- Average load current (continuous): 21.7 A
- The above load current is 4% higher than the allowable ampacity without adders.
- The conductor temperature never reached its rated temperature
- Its temperature never exceeded 85°C
- Its temperature exceeded 80°C for only 1.5% of the time
- The adders in Table 310.15(B)(3)(c) of the NEC are not necessary.

Committee Statement
Committee Action: Rejected
Resolution: The submitted data did not include evidence of wiring methods placed in direct contact with the rooftop surface. The evidence that was submitted strongly supports the actions taken in FR 1503 to delete any temperature adders for wiring methods that maintain separation from the rooftop surface.
(3) Adjustment Factors.

(a) More than Three Current-Carrying Conductors. Where the number of current-carrying conductors in a raceway or cable exceeds three, or where single conductors or multiconductor cables are installed without maintaining spacing for a continuous length longer than 600 mm (24 in.) and are not installed in raceways, the allowable ampacity of each conductor shall be reduced as shown in Table 310.15(B)(3)(a). Section 310.15(A)(2) exception shall not apply. Each current-carrying conductor of a paralleled set of conductors shall be counted as a current-carrying conductor.

Where conductors of different systems, as provided in 300.3, are installed in a common raceway or cable, the adjustment factors shown in Table 310.15(B)(3)(a) shall apply only to the number of power and lighting conductors (Articles 210, 215, 220, and 230).

Informational Note No. 1: See Annex B for adjustment factors for more than three current-carrying conductors in a raceway or cable with load diversity.

Informational Note No. 2: See 366.23 for adjustment factors for conductors and ampacity for bare copper and aluminum bars in auxiliary gutters and 376.22(B) for adjustment factors for conductors in metal wireways.

1. Where conductors are installed in cable trays, the provisions of 392.80 shall apply.

2. Adjustment factors shall not apply to conductors in raceways having a length not exceeding 600 mm (24 in.).

3. Adjustment factors shall not apply to underground conductors entering or leaving an outdoor trench if those conductors have physical protection in the form of rigid metal conduit, intermediate metal conduit, rigid polyvinyl chloride conduit (PVC), or reinforced thermosetting resin conduit (RTRC) having a length not exceeding 3.05 m (10 ft), and if the number of conductors does not exceed four.

4. Adjustment factors shall not apply to Type AC cable or to Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. Each cable has not more than three current-carrying conductors.
   c. The conductors are 12 AWG copper.
   d. Not more than 20 current-carrying conductors are installed without maintaining spacing, are stacked, or are supported on "bridle rings."

Exception: A 60 percent adjustment factor shall be applied if the current-carrying conductors in these cables that are stacked or bundled longer than 600 mm (24 in.) without maintaining spacing exceed 20.

5. An adjustment factor of 60 percent shall be applied to Type AC cable or Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. The number of current-carrying conductors exceeds 20.
   c. The cables are stacked or bundled longer that 600 mm (24 in.) without spacing being maintained.

**Committee Statement**

- **Committee Action:** Rejected but see related SR
- **Resolution:** SR-1506-NFPA 70-2015
- **Statement:**

  Statement: No instances of compromised safety were submitted to the panel to support the prohibition against using the Exception in 310.15(A)(2). While the language in 310.15(A)(2) Exception and 310.15(B)(3)(a) may conflict in a limited number of cases, more information needs to be submitted to the panel.

  The rewrite of 310.15(B)(3)(a)(4) exception to “4” makes it clear that the exception applies to the same size, type and construction of cables, but that an adjustment factor is necessary for a different installation condition than indicated in list item (d). The exception language and placement is in accordance with the NEC Style Manual 2.6.1 and addresses the CC concerns.

  The committee agrees to delete the language in 310.15(B)(3)(a)(5) as recommended in PI 3375 and PC 1041; those changes were not properly reflected in the First Draft.
Adjustment Factors.

(a) More than Three Current-Carrying Conductors. Where the number of current-carrying conductors in a raceway or cable exceeds three, or where single conductors or multiconductor cables are installed without maintaining spacing for a continuous length longer than 600 mm (24 in.) and are not installed in raceways, the allowable ampacity of each conductor shall be reduced as shown in Table 310.15(B)(3)(a). Section 310.15(A)(2) exception shall not apply. Each current-carrying conductor of a paralleled set of conductors shall be counted as a current-carrying conductor.

Where conductors of different systems, as provided in 300.3, are installed in a common raceway or cable, the adjustment factors shown in Table 310.15(B)(3)(a) shall apply only to the number of power and lighting conductors (Articles 210, 215, 220, and 230).

Informational Note No. 1: See Annex B for adjustment factors for more than three current-carrying conductors in a raceway or cable with load diversity.

Informational Note No. 2: See 366.23 for adjustment factors for conductors and ampacity for bare copper and aluminum bars in auxiliary gutters and 376.22(B) for adjustment factors for conductors in metal wireways.

(1) Where conductors are installed in cable trays, the provisions of 392.80 shall apply.

(2) Adjustment factors shall not apply to conductors in raceways having a length not exceeding 600 mm (24 in.).

(3) Adjustment factors shall not apply to underground conductors entering or leaving an outdoor trench if those conductors have physical protection in the form of rigid metal conduit, intermediate metal conduit, rigid polyvinyl chloride conduit (PVC), or reinforced thermosetting resin conduit (RTRC) having a length not exceeding 3.05 m (10 ft), and if the number of conductors does not exceed four.

(4) Adjustment factors shall not apply to Type AC cable or to Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. Each cable has not more than three current-carrying conductors.
   c. The conductors are 12 AWG copper.
   d. Not more than 20 current-carrying conductors are installed without maintaining spacing, are stacked, or are supported on “bridle rings.”

Exception: A 60 percent adjustment factor shall be applied if the current-carrying conductors in these cables that are stacked or bundled longer than 600 mm (24 in.) without maintaining spacing exceeds 20.

(5) An adjustment factor of 60 percent shall be applied to Type AC cable or Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. The number of current-carrying conductors exceeds 20.
   c. The cables are stacked or bundled longer that 600 mm (24 in.) without spacing being maintained.

Statement of Problem and Substantiation for Public Comment

This comment urges the Committee to recognize and accept the science that resulted in Table 310.15(B)(3)(c) and text that was included in the 2014 Edition of the NEC. The table and text from the 2014 NEC should be restored. The accuracy of the testing performed that resulted in the text and table was verified by Underwriters Laboratories in a Fact Finding Report. No such verified science has been provided by the naysayers who have submitted faulty recommendations that have been accepted by this Committee. I urge the Committee to do the right thing and accept the documented and verified science.

Submittal Date: Wed Sep 23 10:59:47 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The submitter’s substantiation is incorrect. The studies submitted to the committee in previous cycles on behalf of the Copper Development Association were not comprehensive and did not consider the effects of the multiple factors present in energized conductor installations. Notably, those studies did not include any energized conductors. In reviewing the totality of the record over the last few cycles, it is apparent that the rooftop adders are unnecessary for most installations. The only remaining item of contention is wiring methods placed in direct contact with rooftop surfaces. No substantive information was submitted to refute the findings of the Correlating Committee Task Group, and the language accepted in FR 1503 is considered to be correct based on available data and adequate to ensure safe installations.
Adjustment Factors.

(a) More than Three Current-Carrying Conductors. Where the number of current-carrying conductors in a raceway or cable exceeds three, or where single conductors or multiconductor cables are installed without maintaining spacing for a continuous length longer than 600 mm (24 in.) and are not installed in raceways, the allowable ampacity of each conductor shall be reduced as shown in Table 310.15(B)(3)(a). Section 310.15(A)(2) exception shall not apply. Each current-carrying conductor of a paralleled set of conductors shall be counted as a current-carrying conductor.

Where conductors of different systems, as provided in 300.3, are installed in a common raceway or cable, the adjustment factors shown in Table 310.15(B)(3)(a) shall apply only to the number of power and lighting conductors (Articles 210, 215, 220, and 230).

Informational Note No. 1: See Annex B for adjustment factors for more than three current-carrying conductors in a raceway or cable with load diversity.

Informational Note No. 2: See 366.23 for adjustment factors for conductors and ampacity for bare copper and aluminum bars in auxiliary gutters and 376.22(B) for adjustment factors for conductors in metal wireways.

(1) Where conductors are installed in cable trays, the provisions of 392.80 shall apply.

(2) Adjustment factors shall not apply to conductors in raceways having a length not exceeding 600 mm (24 in.).

(3) Adjustment factors shall not apply to underground conductors entering or leaving an outdoor trench if those conductors have physical protection in the form of rigid metal conduit, intermediate metal conduit, rigid polyvinyl chloride conduit (PVC), or reinforced thermosetting resin conduit (RTRC) having a length not exceeding 3.05 m (10 ft), and if the number of conductors does not exceed four.

(4) Adjustment factors shall not apply to Type AC cable or to Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. Each cable has not more than three current-carrying conductors.
   c. The conductors are 12 AWG copper.
   d. Not more than 20 current-carrying conductors are installed without maintaining spacing, are stacked, or are supported on "bridle rings."
   Exception: A 60 percent adjustment factor shall be applied if the current-carrying conductors in these cables that are stacked or bundled longer than 600 mm (24 in.) without maintaining spacing exceeds 20.

(5) An adjustment factor of 60 percent shall be applied to Type AC cable or Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. The number of current-carrying conductors exceeds 20.
   c. The cables are stacked or bundled longer that 600 mm (24 in.) without spacing being maintained.

1 Number of conductors is the total number of conductors in the raceway or cable, including spare conductors. The count shall be adjusted in accordance with 310.15(B)(6) and (6). The count shall not include conductors that are connected to electrical components that cannot be simultaneously energized.

(b) Raceway Spacing. Spacing between raceways shall be maintained.

(c) Raceways and Cables Exposed to Sunlight on Rooftops. Where raceways or cables are exposed to direct sunlight on or above rooftops, raceways or cables shall be installed a minimum distance above the roof to the bottom of the raceway or cable of 23 mm ( ¾ in.). Where the distance above the roof to the bottom of the raceway is less than 23 mm ( ¾ in.), a temperature adder of 33°C (60°F) shall be added to the outdoor temperature to determine the applicable ambient temperature for application of the correction factors in Table 310.15(B)(2)(a) or Table 310.15(B)(2)(b).

Exception: Type XHHW-2, Type RHW-2 and Type PV thermoset insulated conductors shall not be subject to this ampacity adjustment.

Informational Note: One source for the ambient temperatures in various locations is the ASHRAE Handbook — Fundamentals.
Thermoset insulated conductors (including XHHW-2, PV and RHW-2) are capable of handling the heating effect of direct sunlight on rooftops with no safety concerns. Thermoset insulation is superior to thermoplastic insulation in high heat applications. Industry standards from IEEE, ICEA and NEMA indicate that thermoset insulation is adequate for much higher temperatures than those experienced on rooftops for the period of time indicated. There are many types of thermoset insulation allowed in the NEC: XHHW-2, RHW-2, and PV wire are a few of the more common types. Of these, XHHW-2 has the thinnest wall requirements and the lowest electrical testing requirements in the UL standards. There is no reason to believe that the other thermoset types would not perform as well as or better than XHHW-2.

Submittal Date: Wed Sep 23 22:43:39 EDT 2015

Committee Statement
Committee Action: Rejected
Resolution: The additional insulation types proposed are of equal or more robust construction and composition than the currently allowed XHHW-2. More information is needed to guarantee that these conductor types will perform the same as XHHW-2 under the test conditions that warranted the exception for these conductors to be exempt from the requirements in 310.15(B)(3)(c). The panel recommends the submitter provide a comparison of the testing procedures and properties be submitted for the next cycle.
(3) Adjustment Factors.

(a) More than Three Current-Carrying Conductors. Where the number of current-carrying conductors in a raceway or cable exceeds three, or where single conductors or multi-conductor cables are installed without maintaining spacing for a continuous length longer than 600 mm (24 in.) and are not installed in raceways, the allowable ampacity of each conductor shall be reduced as shown in Table 310.15(B)(3)(a). Exception shall not apply. Each current-carrying conductor of a paralleled set of conductors shall be counted as a current-carrying conductor.

Where conductors of different systems, as provided in 300.3, are installed in a common raceway or cable, the adjustment factors shown in Table 310.15(B)(3)(a) shall apply only to the number of power and lighting conductors (Articles 210, 215, 220, and 230).

Informational Note No. 1: See Annex B for adjustment factors for more than three current-carrying conductors in a raceway or cable with load diversity.

Informational Note No. 2: See 366.23 for adjustment factors for conductors and ampacity for bare copper and aluminum bars in auxiliary gutters and 376.22(B) for adjustment factors for conductors in metal wireways.

(1) Where conductors are installed in cable trays, the provisions of 392.80 shall apply.

(2) Adjustment factors shall not apply to conductors in raceways having a length not exceeding 600 mm (24 in.).

(3) Adjustment factors shall not apply to underground conductors entering or leaving an outdoor trench if those conductors have physical protection in the form of rigid metal conduit, intermediate metal conduit, rigid polyvinyl chloride conduit (PVC), or reinforced thermosetting resin conduit (RTRC) having a length not exceeding 3.05 m (10 ft), and if the number of conductors does not exceed four.

(4) Adjustment factors shall not apply to Type AC cable or to Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. Each cable has not more than three current-carrying conductors.
   c. The conductors are 12 AWG copper.
   d. Not more than 20 current-carrying conductors are installed without maintaining spacing, are stacked, or are supported on "bride rings."

   Exception: A 60 percent adjustment factor shall be applied if the current-carrying conductors in these cables that are stacked or bundled longer than 600 mm (24 in.) without maintaining spacing exceeds 20.

(5) An adjustment factor of 60 percent shall be applied to Type AC cable or Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. The number of current-carrying conductors exceeds 20.
   c. The cables are stacked or bundled longer that 600 mm (24 in.) without spacing being maintained.

1Number of conductors is the total number of conductors in the raceway or cable, including spare conductors. The count shall be adjusted in accordance with 310.15(B)(5) and (6). The count shall not include conductors that are connected to electrical components that cannot be simultaneously energized.

(b) Raceway Spacing. Spacing between raceways shall be maintained.

(c) Raceways and Cables Exposed to Sunlight on rooftops. Where raceways or cables are exposed to direct sunlight on or above rooftops, raceways or cables shall be installed a minimum distance above the roof to the bottom of the raceway or cable of 23 mm ( ⅞ in.). Where the distance above the roof to the bottom of the raceway is less than 23 mm ( ⅞ in.), a temperature adder of 33°C (60°F) shall be added to the outdoor temperature to determine the applicable ambient temperature for application of the correction factors in Table 310.15(B)(2)(a) or Table 310.15(B)(2)(b).

Exception: Type XHHW-2 insulated conductors shall not be subject to this ampacity adjustment.

Informational Note: One source for the ambient temperatures in various locations is the ASHRAE Handbook — Fundamentals.

Statement of Problem and Substantiation for Public Comment

No substantiation was provided in any of the public inputs to warrant adding the new language to 310.15(B)(3)(a). The new language
would not allow the option to use the exception to 310.15(A)(2) where there are more than three current carrying conductors in a raceway or cable. The exception allows the higher ampacity to be used for either 10% or 10' whichever is less. This exception should apply for either temperature correction or adjustment for number of conductors over three in a raceway or cable.

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-1506-NFPA 70-2015
Statement: Statement: No instances of compromised safety were submitted to the panel to support the prohibition against using the Exception in 310.15(A)(2). While the language in 310.15(A)(2) Exception and 310.15(B)(3)(a) may conflict in a limited number of cases, more information needs to be submitted to the panel.

The rewrite of 310.15(B)(3)(a)(4) exception to “4” makes it clear that the exception applies to the same size, type and construction of cables, but that an adjustment factor is necessary for a different installation condition than indicated in list item (d). The exception language and placement is in accordance with the NEC Style Manual 2.6.1 and addresses the CC concerns.

The committee agrees to delete the language in 310.15(B)(3)(a)(5) as recommended in PI 3375 and PC 1041; those changes were not properly reflected in the First Draft.
(3) Adjustment Factors.
More than Three Current-Carrying Conductors. Where the number of current-carrying conductors in a raceway or cable exceeds three, or where single conductors or multiconductor cables are installed without maintaining spacing for a continuous length longer than 600 mm (24 in.) and are not installed in raceways, the allowable ampacity of each conductor shall be reduced as shown in Table 310.15(B)(3)(a). Section 310.15(A)(2) exception shall not apply. Each current-carrying conductor of a paralleled set of conductors shall be counted as a current-carrying conductor.

Where conductors of different systems, as provided in 300.3, are installed in a common raceway or cable, the adjustment factors shown in Table 310.15(B)(3)(a) shall apply only to the number of power and lighting conductors (Articles 210, 215, 220, and 230).

Informational Note No. 1: See Annex B for adjustment factors for more than three current-carrying conductors in a raceway or cable with load diversity.

Informational Note No. 2: See 366.23 for adjustment factors for conductors and ampacity for bare copper and aluminum bars in auxiliary gutters and 376.22(B) for adjustment factors for conductors in metal wireways.

(1) Where conductors are installed in cable trays, the provisions of 392.80 shall apply.

(2) Adjustment factors shall not apply to conductors in raceways having a length not exceeding 600 mm (24 in.).

(3) Adjustment factors shall not apply to underground conductors entering or leaving an outdoor trench if those conductors have physical protection in the form of rigid metal conduit, intermediate metal conduit, rigid polyvinyl chloride conduit (PVC), or reinforced thermosetting resin conduit (RTRC) having a length not exceeding 3.05 m (10 ft), and if the number of conductors does not exceed four.

(4) Adjustment factors shall not apply to Type AC cable or to Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. Each cable has not more than three current-carrying conductors.
   c. The conductors are 12 AWG copper.
   d. Not more than 20 current-carrying conductors are installed without maintaining spacing, are stacked, or are supported on “bridge rings.”
   Exception: A 60 percent adjustment factor shall be applied if the current-carrying conductors in these cables that are stacked or bundled longer than 600 mm (24 in.) without maintaining spacing exceeds 20.

(5) An adjustment factor of 60 percent shall be applied to Type AC cable or Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. The number of current carrying conductors exceeds 20.
   c. The cables are stacked or bundled longer that 600 mm (24 in.) without spacing being maintained.

¹Number of conductors is the total number of conductors in the raceway or cable, including spare conductors. The count shall be adjusted in accordance with 310.15(B)(5) and (6). The count shall not include conductors that are connected to electrical components that cannot be simultaneously energized.

(b) Raceway Spacing. Spacing between raceways shall be maintained.

(c) Raceways and Cables Exposed to Sunlight on Rooftops.

Where raceways or cables are exposed to direct sunlight on or above rooftops, raceways or cables shall be installed a minimum distance above the roof to the bottom of the raceway or cable of 23 mm (7/8 in.), the distance above the roof to the bottom of the raceway is less than 23 mm (7/8 in.), a temperature adder of 33°C (60°F).

The adjustments shown in Table 310.15(B)(3)(c) shall be added to the outdoor temperature to determine the applicable ambient temperature for application of the correction factors in Table 310.15(B)(2)(a) or Table 310.15(B)(2)(b).

Table 310.15(B)(3)(c) Ambient Temperature Adjustment for Rooftops

Rooftops
Statement of Problem and Substantiation for Public Comment

First Revision 1503
Comment to NEC 310.15(B)(3)

My 30-plus-year practice as a metallurgical and materials consultant (BS Met. E. (Lafayette College), M.S. (Penn State), Ph.D.
Metallurgy (Case Institute of Technology)) is located in a suburb of Tucson, Arizona, where daytime summer temperatures can exceed 45 C (113 F) and daily highs can pass 38 C (100 F) for three months in a row. Here, it is literally possible to fry eggs on pavement or, more to the subject of this meeting, on an unshaded rooftop. Ambient temperature inside rooftop-mounted electrical conduit is a valid and very real design consideration in the Southwest, as it is in the South and a surprising portion of the rest of the country.

Adding to the risk is the common practice of mounting large, heavily and continuously loaded air conditioners and/or evaporative coolers on the flat roofs of commercial buildings, malls, shopping centers and the like. Such facilities do not all employ on-site electricians to conduct appropriate inspection and maintenance. Material deterioration can proceed unchecked under such circumstances, and it is quite possible that insulation failures in overheated, conduit-enclosed feeder cables have led to building fires in the past. Unfortunately, the direct cause of the resulting fires is impossible to ascertain after the fact (the evidence being destroyed) and, failing the presence of a certified fire inspector backed up by a suitably equipped laboratory, difficult to report (Who would do the reporting, and to whom?). But just because the root cause (overheated conduit environments) rarely if ever makes it to the pages of the morning paper, its existence cannot and should not be ruled out.

Ambient adjustments and “rooftop adders” are demonstrably important for fire prevention and public safety. Insulation deterioration due to excessive intra-conduit temperatures, i.e., beyond the insulation’s capability and rating, is well known and can be hazardous. We need only look to electric motor and transformer manufacturers for a practical rule-of-thumb: exposure of insulation to temperatures higher than 10 degrees Celsius above the insulation’s rated operating temperature for more than six to eight hours cuts equipment life by one-half. In Tucson, we enjoy 300-plus days of sunshine a year. If our roof-mounted air conditioner motors fail —as they regularly do—why cannot conduit-encased cables also be at risk?

It is for these reasons that I strongly object to the removal of rooftop adders as now found in Table 350.15 (B)(3)(c) from NEC 2017. The question of intra-conduit thermal environments under strong insulation is clearly an issue of fire prevention and public safety.

For the sake of full disclosure: my clients include a variety of metals-producing, metals-related and metals-using organizations, and in this instance, the Copper Development Association (CDA), I became aware of the rooftop adder issue several years ago during job for TLCS Inc., dealing with insulation material properties. At the time, my client was conducting early research on conduit temperatures for CDA, work that was subsequently expanded in considerable detail by UL and documented in two UL Fact-Finding Studies, an earlier EATS study report, as well as a peer-reviewed IEEE- IAS paper. In my opinion, the UL Fact-Finding Studies (and earlier work cited above) were conducted with appropriate technical and scientific rigor. Investigations of all variables addressed were properly documented, methodology was clearly described, data were correctly recorded and the conclusions drawn were technically reasonable and justifiable. Peer review of the published results substantiates this assertion.

My specific comments regarding the substitution of a revised Table 350.15 (B)(3)(c) for the approved version published in NEC 2014 include the following:
• We should not base changes in NEC 2017 on junk science. The rooftop adder values contained in the existing NEC 2014 Table 350.15 (B)(3)(c) are based on more than a decade of thorough, broad-based, technical research. The Rooftop Adder Table proposed to be published in NEC 2017 should/must be based on precisely that level of rigorous and thorough investigations, this literally being a potential matter of life or death. To my knowledge, and based upon my review of the UNLV study, a brief PowerPoint presentation, etc. this is certainly not the case. One example: cable loading for the single test described in the UNLV study was less than one-half of the Code limit for the AWG 12-gage wire used. Of course the temperature rise will be lower than that permitted under NEC 2014 under those circumstances.
• Specifically, while the proposed replacement table calls for retaining the current table’s rooftop adder of 33°C at “less than one inch” above the roof surface, it changes the value of all adders for conduit placement distances above one inch to zero. (The current table sets the value of the adder at 17 C for five inches above the surface, for example.) That value, zero, is arbitrary and scientifically
The submitter's contention that rooftop fires have been caused by conductor insulation failure inside conduits is unsupported. The submitter does not describe how mid-span insulation failures within metallic conduits cause building fires without operating overcurrent protective devices. The submitter is directed to the NFPA Fire Analysis and Research division for fire statistics and reports. Insulation deterioration within conduits due to exposure to direct sunlight is not well-known; reports submitted in previous cycles from panel members representing the International Association of Electrical Inspectors and the American Chemistry Council lead to the opposite conclusion. Robert Huddleston's Rooftop Wiring Study demonstrated that rooftop conductors installed in a Southern US location (sized prior to the rooftop temperature adders in the NEC) did not suffer material deterioration after many years (14 years for one location, approximately 40 for another) of service. Evidence has been submitted to the panel in multiple studies showing that the operating temperature of insulated conductors is not being exceeded when installed in accordance with the rules in the NEC (even without the rooftop adders). There has been no evidence presented to the panel of rooftop conductors failing due to solar heating, or of building fires caused by such conductors. While we respect the peer review process, engineers on this panel have seen multiple instances of peer reviewed papers with opposite conclusions; being peer-reviewed doesn't mean the conclusions of a paper are necessarily correct or actionable. The actions of this panel in FR 1503 are not based on junk science; they are based on evidence submitted from multiple credible sources. The submitter failed to account for the required temperature correction and adjustment factors present in Article 310 and required to determine the ampacity of a conductor under conditions of use. The panel agrees that there is not an "abrupt temperature discontinuity" at one inch above the rooftop surface; we look forward to future submissions with a more justifiable rooftop adder than the currently accepted 60F. The temperature corrections and adjustment factors in the NEC apply to both aluminum and copper conductors. Cable loading for the UNLV study was based on the ampacity and temperature tables in the NEC. The UL studies did not provide for any loading of conductors, and so this important information is absent from those reports. One of the conclusions of the first UL report was that "temperature rise above ambient for wiring systems mounted 0.5, 3.5, and 12.0 inches above the roof were not affected significantly by distance. Therefore distances greater than 0.5 inches can be considered far from the roof and roof distance does not need to be a consideration in calculating temperature rise." The positioning of the UNLV wiring systems at 8" above the roof is thus completely representative of heating effects related to wiring system position above the roof.
(3) Adjustment Factors.
More than Three Current-Carrying Conductors. Where the number of current-carrying conductors in a raceway or cable exceeds three, or where single conductors or multi-conductor cables are installed without maintaining spacing for a continuous length longer than 600 mm (24 in.) and are not installed in raceways, the allowable ampacity of each conductor shall be reduced as shown in Table 310.15(B)(3)(a). Section 310.15(A)(2) exception shall not apply. Each current-carrying conductor of a paralleled set of conductors shall be counted as a current-carrying conductor.

Where conductors of different systems, as provided in 300.3, are installed in a common raceway or cable, the adjustment factors shown in Table 310.15(B)(3)(a) shall apply only to the number of power and lighting conductors (Articles 210, 215, 220, and 230).

Informational Note No. 1: See Annex B for adjustment factors for more than three current-carrying conductors in a raceway or cable with load diversity.

Informational Note No. 2: See 366.23 for adjustment factors for conductors and ampacity for bare copper and aluminum bars in auxiliary gutters and 376.22(B) for adjustment factors for conductors in metal wireways.

(1) Where conductors are installed in cable trays, the provisions of 392.80 shall apply.

(2) Adjustment factors shall not apply to conductors in raceways having a length not exceeding 600 mm (24 in.).

(3) Adjustment factors shall not apply to underground conductors entering or leaving an outdoor trench if those conductors have physical protection in the form of rigid metal conduit, intermediate metal conduit, rigid polyvinyl chloride conduit (PVC), or reinforced thermostetting resin conduit (RTRC) having a length not exceeding 3.05 m (10 ft), and if the number of conductors does not exceed four.

(4) Adjustment factors shall not apply to Type AC cable or to Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. Each cable has not more than three current-carrying conductors.
   c. The conductors are 12 AWG copper.
   d. Not more than 20 current-carrying conductors are installed without maintaining spacing, are stacked, or are supported on “bridle rings.”

   Exception: A 60 percent adjustment factor shall be applied if the current-carrying conductors in these cables that are stacked or bundled longer than 600 mm (24 in.) without maintaining spacing exceeds 20.

(5) An adjustment factor of 60 percent shall be applied to Type AC cable or Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. The number of current-carrying conductors exceeds 20.
   c. The cables are stacked or bundled longer that 600 mm (24 in.) without spacing being maintained.

1Number of conductors is the total number of conductors in the raceway or cable, including spare conductors. The count shall be adjusted in accordance with 310.15(B)(5) and (6). The count shall not include conductors that are connected to electrical components that cannot be simultaneously energized.

(b) Raceway Spacing. Spacing between raceways shall be maintained.

(c) Raceways and Cables Exposed to Sunlight on Rooftops.

Where raceways or cables are exposed to direct sunlight on or above rooftops, raceways or cables shall be installed a minimum distance above the roof to the bottom of the raceway or cable of 33 mm (1 1/4 in.). Where the distance above the roof to the bottom of the raceway is less than 23 mm (7/8 in.), a temperature adder of 33°C (60°F) the adjustments shown in Table 310.15(B)(3)(c) shall be added to the outdoor temperature.

To determine the applicable ambient temperature for application of the correction factors in Table 310.15(B)(2)(a), or Table 310.15(B)(2)(b),

Exception: Type XHHW-2 insulated conductors shall not be subject to this ampacity adjustment.

### Statement of Problem and Substantiation for Public Comment

Supporting information for – FR 1503

**NEC 310.15(B)(3)**

Panel 6 members were not provided full access to the reports used in working groups to develop consensus occurring the day before code hearings, thus improperly biasing final actions by improperly restricting access to the documentation. Task group opinions and the UNLV report were similarly incomplete prior to the code panel meeting. The result was a rushing and crippling of the process. The panel then accepted unscientific, untested statements as in the case for both the task group presentation and the UNLV research report. The task group evaluated some mathematical modeling. The mathematics, assumptions and variables of this modeling were not reviewed by any other outside third party. The assumptions and task group statements resulting from this modeling have been disproven by previous research, and can be disproven repeatedly in further research. No written report was ever generated from this work which could then be reviewed by outside parties. Numeric modeling was not peer-reviewed and not verified by any research work. Modeling as submitted conflicted with previously developed test data as certified by the Fact Finding investigations and as covered in IEEE peer reviewed transactions. Assumptions were incorrect. Wicking or thermal transfer was mentioned as a factor in the task group presentation but experienced UL panel members have testified that heat does not significantly move along the conductor material to a cooler portion or from a hot spot to cold cooling a hot spot on a conductor. As for the UNLV Research project, this was filled with the most glaring errors. Obscure calculations were used to demonstrate that a portable cord plug connected load, a continuous load and other values would reduce the allowable ampacity of a 12 AWG 90C copper conductor to 13.3 amps. By loading the conductor to 13.3 amps, UNLV then would erroneously theorize from this loading, and derived temperatures, that no conductor allowable temperature would ever be exceeded. A much more realistic examination would be a load, such as an air conditioning load, operating close to 100% of the allowable ampacity at just less than three hours (2.9 hours), relaxed sparingly, allowed to cool for a few minutes and then restarted and cycled this way repeatedly. This circuit could comply with the NEC requirements. A four foot vertical riser was created in each raceway and cable sample, enabling an updraft not typical of most installations. The updraft provided unusual and excessive air movement inside the raceway samples nullifying results. The air movement was also not accounted for in findings. Additionally, the thermocouple sensors were placed at the lower portion of raceway samples, however, the highest temperatures would be experienced in the upper elevations where no sensors were placed. For cable type samples the interior air movement was not present because of the densely packed construction of the cable samples. The effect of this can be seen in the black MC Cable which achieved temperature of 22.6 C unloaded at 8 inches above the roof. The temperature of the MC Cable sample exceeded the required 17C adjustment of NEC table 310.15(B)(3)(c) confirming the original research. It is obvious from this fact, that only selected findings were important to the authors of this report.

### Submitter Information Verification

**Submitter Full Name:** TRAVIS LINDSEY  
**Organization:** TLC SERVICES Inc  
**Street Address:**  
**City:**  
**State:**  
**Zip:**  
**Submittal Date:** Fri Sep 25 10:10:10 EDT 2015
Committee Statement

Committee Action: Rejected

Resolution: The substantiation provided by the submitter is incorrect. The referenced reports were provided to the task group and distributed to the full committee at the meeting. No committee members other than the task group requested the reports prior to the meeting, even though the public inputs clearly indicated that such reports were available for their review. It is the responsibility of the committee members to review the materials prior to the committee meeting. The UNLV report was submitted and received by NFPA in compliance with the published deadline. The task group recommendations were available to the full committee prior to the meeting. • The submitter indicates that "Assumptions were incorrect," but does not specify which assumptions. It is of interest that the submitter referred to the NEC calculations in the UNLV report as obscure, and the panel directs the submitter to review Article 310 of the National Electrical Code. The panel does not accept that a more realistic examination would include an air conditioner running for 2.9 hours, turned off for a short time, then turned on for another 2.9 hours. However, the panel will review any testing submitted. Thermocouples were placed at several locations in the wiring methods, including both the highest and lowest elevations. The wiring methods terminated in wireways at both ends, limiting potential airflow. The UNLV research from 2014 was documented in a report that was provided to CMP6. Significant information regarding temperature rise on insulated conductors due to solar heating is provided by test data, as well as examination of actual conductors exposed to rooftop temperature conditions over time. The UNLV reports and Robert Huddleston's report provided this information.
(3) Adjustment Factors.

(a) More than Three Current-Carrying Conductors. Where the number of current-carrying conductors in a raceway or cable exceeds three, or where single conductors or multi-conductor cables are installed without maintaining spacing for a continuous length longer than 600 mm (24 in.) and are not installed in raceways, the allowable ampacity of each conductor shall be reduced as shown in Table 310.15(B)(3)(a). Section 310.15(A)(2) exception shall not apply. Each current-carrying conductor of a paralleled set of conductors shall be counted as a current-carrying conductor.

Where conductors of different systems, as provided in 300.3, are installed in a common raceway or cable, the adjustment factors shown in Table 310.15(B)(3)(a) shall apply only to the number of power and lighting conductors (Articles 210, 215, 220, and 230).

Informational Note No. 1: See Annex B for adjustment factors for more than three current-carrying conductors in a raceway or cable with load diversity.

Informational Note No. 2: See 366.23 for adjustment factors for conductors and ampacity for bare copper and aluminum bars in auxiliary gutters and 376.22(B) for adjustment factors for conductors in metal wireways.

(1) Where conductors are installed in cable trays, the provisions of 392.80 shall apply.

(2) Adjustment factors shall not apply to conductors in raceways having a length not exceeding 600 mm (24 in.).

(3) Adjustment factors shall not apply to underground conductors entering or leaving an outdoor trench if those conductors have physical protection in the form of rigid metal conduit, intermediate metal conduit, rigid polyvinyl chloride conduit (PVC), or reinforced thermosetting resin conduit (RTRC) having a length not exceeding 3.05 m (10 ft), and if the number of conductors does not exceed four.

(4) Adjustment factors shall not apply to Type AC cable or to Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. Each cable has not more than three current-carrying conductors.
   c. The conductors are 12 AWG copper.
   d. Not more than 20 current-carrying conductors are installed without maintaining spacing, are stacked, or are supported on “bridle rings.”

   Exception: A 60 percent adjustment factor shall be applied if the current-carrying conductors in these cables that are stacked or bundled longer than 600 mm (24 in.) without maintaining spacing exceeds 20.

(5) An adjustment factor of 60 percent shall be applied to Type AC cable or Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. The number of current-carrying conductors exceeds 20.
   c. The cables are stacked or bundled longer that 600 mm (24 in.) without spacing being maintained.

Number of conductors is the total number of conductors in the raceway or cable, including spare conductors. The count shall be adjusted in accordance with 310.15(B)(6) and (6). The count shall not include conductors that are connected to electrical components that cannot be simultaneously energized.

(b) Raceway Spacing. Spacing between raceways shall be maintained.

(c) Raceways and Cables Exposed to Sunlight on Rooftops. Where raceways or cables are exposed to direct sunlight on or above rooftops, raceways or cables shall be installed a minimum distance above the roof to the bottom of the raceway or cable of 23 mm ( ⅞ in.). Where the distance above the roof to the bottom of the raceway is less than 23 mm ( ⅞ in.), a temperature adder of 33°C (60°F) shall be added to the outdoor temperature to determine the applicable ambient temperature for application of the correction factors in Table 310.15(B)(2)(a) or Table 310.15(B)(2)(b).

   Exception: Type XHHW-2 insulated conductors shall not be subject to this ampacity adjustment.

Informational Note: One source for the ambient temperatures in various locations is the ASHRAE Handbook—Fundamentals.

Statement of Problem and Substantiation for Public Comment

There seems to be no technical substantiation in the public inputs to remove the allowances of 310.15(A)(2) Ex.
Committee Action: Rejected but see related SR
Resolution: SR-1506-NFPA 70-2015
Statement: No instances of compromised safety were submitted to the panel to support the prohibition against using the
Exception in 310.15(A)(2). While the language in 310.15(A)(2) Exception and 310.15(B)(3)(a) may conflict in a limited
number of cases, more information needs to be submitted to the panel.

The rewrite of 310.15(B)(3)(a)(4) exception to "4" makes it clear that the exception applies to the same size, type and
construction of cables, but that an adjustment factor is necessary for a different installation condition than indicated in list
item (d). The exception language and placement is in accordance with the NEC Style Manual 2.6.1 and addresses the
CC concerns.

The committee agrees to delete the language in 310.15(B)(3)(a)(5) as recommended in PI 3375 and PC 1041; those
changes were not properly reflected in the First Draft.
### Adjustment Factors.

(a) **More than Three Current-Carrying Conductors.** Where the number of current-carrying conductors in a raceway or cable exceeds three, or where single conductors or multiconductor cables are installed without maintaining spacing for a continuous length longer than 600 mm (24 in.) and are not installed in raceways, the allowable ampacity of each conductor shall be reduced as shown in Table 310.15(B)(3)(a). Section 310.15(A)(2) exception shall not apply. Each current-carrying conductor of a paralleled set of conductors shall be counted as a current-carrying conductor.

Where conductors of different systems, as provided in 300.3, are installed in a common raceway or cable, the adjustment factors shown in Table 310.15(B)(3)(a) shall apply only to the number of power and lighting conductors (Articles 210, 215, 220, and 230).

Informational Note No. 1: See Annex B for adjustment factors for more than three current-carrying conductors in a raceway or cable with load diversity.

Informational Note No. 2: See 366.23 for adjustment factors for conductors and ampacity for bare copper and aluminum bars in auxiliary gutters and 376.22(B) for adjustment factors for conductors in metal wireways.

(1) Where conductors are installed in cable trays, the provisions of 392.80 shall apply.

(2) Adjustment factors shall not apply to conductors in raceways having a length not exceeding 600 mm (24 in.).

(3) Adjustment factors shall not apply to underground conductors entering or leaving an outdoor trench if those conductors have physical protection in the form of rigid metal conduit, intermediate metal conduit, rigid polyvinyl chloride conduit (PVC), or reinforced thermosetting resin conduit (RTTRC) having a length not exceeding 3.05 m (10 ft), and if the number of conductors does not exceed four.

(4) Adjustment factors shall not apply to Type AC cable or to Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. Each cable has not more than three current-carrying conductors.
   c. The conductors are 12 AWG copper.
   d. Not more than 20 current-carrying conductors are installed without maintaining spacing, are stacked, or are supported on "bride rings."

   Exception: A 60 percent adjustment factor shall be applied if the current-carrying conductors in these cables that are stacked or bundled longer than 600 mm (24 in.) without maintaining spacing exceeds 20.

(5) An adjustment factor of 60 percent shall be applied to Type AC cable or Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. The number of current carrying conductors exceeds 20.
   c. The cables are stacked or bundled longer that 600 mm (24 in.) without spacing being maintained.

1Number of conductors is the total number of conductors in the raceway or cable, including spare conductors. The count shall be adjusted in accordance with 310.15(B)(5) and (6). The count shall not include conductors that are connected to electrical components that cannot be simultaneously energized.

(b) **Raceway Spacing.** Spacing between raceways shall be maintained.

(c) **Raceways and Cables Exposed to Sunlight on rooftops.** Where raceways or cables are exposed to direct sunlight on or above rooftops, raceways or cables shall be installed a minimum distance above the roof to the bottom of the raceway or cable of 23 mm (7/8 in.). Where the distance above the roof to the bottom of the raceway is less than 23 mm (7/8 in.), a temperature adder of 33°C (60°F) shall be added to the outdoor temperature to determine the applicable ambient temperature for application of the correction factors in Table 310.15(B)(2)(a) or Table 310.15(B)(2)(b).

Exception: Type XHHW-2 insulated conductors shall not be subject to this ampacity adjustment.

Informational Note: One source for the ambient temperatures in various locations is the ASHRAE Handbook — Fundamentals.

**Statement of Problem and Substantiation for Public Comment**

The Correlating Committee directs that this First Revision, specifically the new exception to 310.15(B)(3)(4)(d), be rewritten to comply...
with the NEC Style Manual. The exception in 310.15(B)(3)(4)(d) is not an exception, it is a rule.

**Committee Action:** Rejected but see related SR  
**Resolution:** SR-1506-NFPA 70-2015  
**Statement:** Statement: No instances of compromised safety were submitted to the panel to support the prohibition against using the Exception in 310.15(A)(2). While the language in 310.15(A)(2) Exception and 310.15(B)(3)(a) may conflict in a limited number of cases, more information needs to be submitted to the panel.

The rewrite of 310.15(B)(3)(a)(4) exception to “4” makes it clear that the exception applies to the same size, type and construction of cables, but that an adjustment factor is necessary for a different installation condition than indicated in list item (d). The exception language and placement is in accordance with the NEC Style Manual 2.6.1 and addresses the CC concerns.

The committee agrees to delete the language in 310.15(B)(3)(a)(5) as recommended in PI 3375 and PC 1041; those changes were not properly reflected in the First Draft.
Adjustment Factors.

(a) More than Three Current-Carrying Conductors. Where the number of current-carrying conductors in a raceway or cable exceeds three, or where single conductors or multiconductor cables are installed without maintaining spacing for a continuous length longer than 600 mm (24 in.) and are not installed in raceways, the allowable ampacity of each conductor shall be reduced as shown in Table 310.15(B)(3)(a). Section 310.15(A)(2) exception shall not apply. Each current-carrying conductor of a paralleled set of conductors shall be counted as a current-carrying conductor.

Where conductors of different systems, as provided in 300.3, are installed in a common raceway or cable, the adjustment factors shown in Table 310.15(B)(3)(a) shall apply only to the number of power and lighting conductors (Articles 210, 215, 220, and 230).

Informational Note No. 1: See Annex B for adjustment factors for more than three current-carrying conductors in a raceway or cable with load diversity.

Informational Note No. 2: See 366.23 for adjustment factors for conductors and ampacity for bare copper and aluminum bars in auxiliary gutters and 376.22(B) for adjustment factors for conductors in metal wireways.

1  Where conductors are installed in cable trays, the provisions of 392.80 shall apply.

(2) Adjustment factors shall not apply to conductors in raceways having a length not exceeding 600 mm (24 in.).

(3) Adjustment factors shall not apply to underground conductors entering or leaving an outdoor trench if those conductors have physical protection in the form of rigid metal conduit, intermediate metal conduit, rigid polyvinyl chloride conduit (PVC), or reinforced thermosetting resin conduit (RTRC) having a length not exceeding 3.05 m (10 ft), and if the number of conductors does not exceed four.

(4) Adjustment factors shall not apply to Type AC cable or to Type MC cable under the following conditions:
  a. The cables do not have an overall outer jacket.
  b. Each cable has not more than three current-carrying conductors.
  c. The conductors are 12 AWG copper.
  d. Not more than 20 current-carrying conductors are installed without maintaining spacing, are stacked, or are supported on “bridle rings.”

   Exception: A 60 percent adjustment factor shall be applied if the current-carrying conductors in these cables that are stacked or bundled longer than 600 mm (24 in.) without maintaining spacing exceeds 20.

(5) An adjustment factor of 60 percent shall be applied to Type AC cable or Type MC cable under the following conditions:
  a. The cables do not have an overall outer jacket.
  b. The number of current carrying conductors exceeds 20.
  c. The cables are stacked or bundled longer that 600 mm (24 in.) without spacing being maintained.

Table 310.15(B)(3)(a) Adjustment Factors for More than Three Current-Carrying Conductors

Submittal Date: Thu Jul 30 10:26:22 EDT 2015

Committee Statement

Committee Action: Rejected

Resolution: The submitter’s substantiation is incorrect. 1) The 33C value was taken from previously submitted work; since no alternate values were provided, the 33C will remain. Additionally, no rooftop cable failures due to sunlight exposure have been submitted to the committee; in fact, numerous examples of insulated conductors that were in service for decades in some of the hottest regions of the country were submitted to the committee as evidence that the rooftop adders were unnecessary. 2) FR 1503 is the culmination of scientific studies submitted by multiple credible sources. 3) Insulations have already been tested and evaluated at higher temperature than insulations manufactured in past decades. Insulated conductors are commonly available at 90C for use in wet locations. FR 1503 is technically sound and ensures the practical safeguarding of persons and property. One of the conclusions of the first UL report was that 'temperature rise above ambient for wiring systems mounted 0.5, 3.5, and 12.0 inches above the roof were not affected significantly by distance. Therefore distances greater than 0.5 inches can be considered far from the roof and roof distance does not need to be a consideration in calculating temperature rise.' The UNLV reports have demonstrated that insulation temperatures inside rooftop cables and conduits do not exceed the temperature ratings of the wire.
**Adjustment Factors.**

(a) **More than Three Current-Carrying Conductors.** Where the number of current-carrying conductors in a raceway or cable exceeds three, or where single conductors or multiconductor cables are installed without maintaining spacing for a continuous length longer than 600 mm (24 in.) and are not installed in raceways, the allowable ampacity of each conductor shall be reduced as shown in Table 310.15(B)(3)(a). Section 310.15(A)(2) exception shall not apply. Each current-carrying conductor of a paralleled set of conductors shall be counted as a current-carrying conductor.

Where conductors of different systems, as provided in 300.3, are installed in a common raceway or cable, the adjustment factors shown in Table 310.15(B)(3)(a) shall apply only to the number of power and lighting conductors (Articles 210, 215, 220, and 230).

Informational Note No. 1: See Annex B for adjustment factors for more than three current-carrying conductors in a raceway or cable with load diversity.

Informational Note No. 2: See 366.23 for adjustment factors for conductors and ampacity for bare copper and aluminum bars in auxiliary gutters and 376.22(B) for adjustment factors for conductors in metal wireways.

1) Where conductors are installed in cable trays, the provisions of 392.80 shall apply.

2) Adjustment factors shall not apply to conductors in raceways having a length not exceeding 600 mm (24 in.).

3) Adjustment factors shall not apply to underground conductors entering or leaving an outdoor trench if those conductors have physical protection in the form of rigid metal conduit, intermediate metal conduit, rigid polyvinyl chloride conduit (PVC), or reinforced thermosetting resin conduit (RTRC) having a length not exceeding 3.05 m (10 ft), and if the number of conductors does not exceed four.

4) Adjustment factors shall not apply to Type AC cable or to Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. Each cable has not more than three current-carrying conductors.
   c. The conductors are 12 AWG copper.
   d. Not more than 20 current-carrying conductors are installed without maintaining spacing, are stacked, or are supported on "bridle rings."

   *Exception:* A 60 percent adjustment factor shall be applied if the current-carrying conductors in these cables that are stacked or bundled longer than 600 mm (24 in.) without maintaining spacing exceeds 20.

5) An adjustment factor of 60 percent shall be applied to Type AC cable or Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. The number of current-carrying conductors exceeds 20.
   c. The cables are stacked or bundled longer that 600 mm (24 in.) without spacing being maintained.

Committee Statement

Committee Action: Rejected
Resolution: The submitter's assertion is incorrect. PI 2808 was resolved by the committee with the following statement: "Multiple test reports were submitted during the 2014 NEC cycle to substantiate the use of XHHW-2 as allowed in the Exception. This decision was upheld by the NEC Correlating Committee, on the floor at the NFPA Association Technical meeting, and by the NFPA Standards Council." See report available on nfpa.org titled "Public Inputs with Responses."
Adjustment Factors.

More than Three Current-Carrying Conductors. Where the number of current-carrying conductors in a raceway or cable exceeds three, or where single conductors or multiconductor cables are installed without maintaining spacing for a continuous length longer than 600 mm (24 in.) and are not installed in raceways, the allowable ampacity of each conductor shall be reduced as shown in Table 310.15(B)(3)(a). Section 310.15(A)(2) exception shall not apply. Each current-carrying conductor of a paralleled set of conductors shall be counted as a current-carrying conductor.

Where conductors of different systems, as provided in 300.3, are installed in a common raceway or cable, the adjustment factors shown in Table 310.15(B)(3)(a) shall apply only to the number of power and lighting conductors (Articles 210, 215, 220, and 230).

Informational Note No. 1: See Annex B for adjustment factors for more than three current-carrying conductors in a raceway or cable with load diversity.

Informational Note No. 2: See 366.23 for adjustment factors for conductors and ampacity for bare copper and aluminum bars in auxiliary gutters and 376.22(B) for adjustment factors for conductors in metal wireways.

(1) Where conductors are installed in cable trays, the provisions of 392.80 shall apply.

(2) Adjustment factors shall not apply to conductors in raceways having a length not exceeding 600 mm (24 in.).

(3) Adjustment factors shall not apply to underground conductors entering or leaving an outdoor trench if those conductors have physical protection in the form of rigid metal conduit, intermediate metal conduit, rigid polyvinyl chloride conduit (PVC), or reinforced thermosetting resin conduit (RTRC) having a length not exceeding 3.05 m (10 ft), and if the number of conductors does not exceed four.

(4) Adjustment factors shall not apply to Type AC cable or to Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. Each cable has not more than three current-carrying conductors.
   c. The conductors are 12 AWG copper.
   d. Not more than 20 current-carrying conductors are installed without maintaining spacing, are stacked, or are supported on “bridle rings.”

   Exception: A 60 percent adjustment factor shall be applied if the current-carrying conductors in these cables that are stacked or bundled longer than 600 mm (24 in.) without maintaining spacing exceeds 20.

(5) An adjustment factor of 60 percent shall be applied to Type AC cable or Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. The number of current carrying conductors exceeds 20.
   c. The cables are stacked or bundled longer that 600 mm (24 in.) without spacing being maintained.

1 Number of conductors is the total number of conductors in the raceway or cable, including spare conductors. The count shall be adjusted in accordance with 310.15(B)(5) and (6). The count shall not include conductors that are connected to electrical components that cannot be simultaneously energized.

Raceway Spacing. Spacing between raceways shall be maintained.

Raceways and Cables Exposed to Sunlight on rooftops. Where raceways or cables are exposed to direct sunlight on above rooftops, raceways or cables shall be installed a minimum distance above the roof to the bottom of the raceway or cable of 23 mm (7/8 in.). Where the distance above the roof to the bottom of the raceway is less than 23 mm (7/8 in.), a temperature adder of 33°C (60°F) shall be added to the outdoor temperature to determine the applicable ambient temperature for application of the correction factors in Table 310.15(B)(2)(a) or Table 310.15(B)(2)(b).

Exception: Type XHHW-2 insulated conductors shall not be subject to this ampacity adjustment.

Informational Note: One source for the ambient temperatures in various locations is the ASHRAE Handbook — Fundamentals.
Statement of Problem and Substantiation for Public Comment

The Panel accepted completely unscientific submissions that defied logic. The so-called "report" and slide presentation contained numerous errors that made the validity and application to temperature in conduits on rooftops completely invalid. Among other errors and methodologies that did not conform to scientific testing, the UNLV report contained the following:

• The UNLV report used a stated load of 13.3 Amps (incorrectly omitting the ballasts) on a wire rated for 30 amps, less than half the rated load.
• The thermocouples were placed at the lowest location in the conduit run, while a bend vertically allowed a chimney effect.
• The chimney effect produced by a four foot vertical rise cooled the conductors, and likely produced air movement within the conduit, although this was not measured.
• The conduit that was measured was connected to a wireway at each end, containing multiple other raceways and cables that were not energized, causing a cooling effect and equalization of temperatures. This would negate the value of this research.
• Cables are not aspirated.
• When an electrical box is at the ends of conduits, the aspiration is restricted, mimicking the cotton UL used at conduit ends.
• Solar irradiance was not measured which would affect temperatures.
• The load was cord and plug connected and continuous. Suppose the load was permanently wired, and non-continuous? If they had chosen a long-running but non-continuous load, such as an air conditioner, the calculation would have resulted in higher temperatures. They incorrectly but purposely used portable loads.
• Had the load been permanently wired, the load could have been increased 25%. We are concerned with the temperature in the conduit, not the over-current device. The research is not applicable to permanently connected or non-portable loads.
• The report did not take different colors of rooftops into account.
• Even this flawed study produced an MC Cable temperature of 22.6 C unloaded at 8 inches above the roof. The present Code shows a 17 C design rise (at a measured solar irradiance and 90 percent of maximum) at this height. If anything, the MC temperature "adder" was exceeded.

In short, conditions for observation were chosen to make the assumptions work and the temperatures measured minimized.

Submitter Information Verification

Submitter Full Name: David Brender
Organization: Copper Development Association
Street Address: 
City: 
State: 
Zip: 
Submittal Date: Wed Sep 09 16:41:51 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The submitter's assertions are incorrect. The submitter's comment regarding conductor loading failed to account for ampacity adjustment and temperature correction factors required by Article 310. Since the load was applied continuously, the 13.33 amp lamp load in the UNLV study is considered 16.67 amps based on 210.19(A)(1)(a). The smallest allowable conductor for this load based on table 310.15(B)16 is a 12 AWG copper. That was the conductor size used in the test, and it has an allowable ampacity of 20A based on the table. Including the rooftop adder adjustment from Table 310.15(B)(3)(a) reduces the allowable current to 15.6A. So the conductors were loaded to more than 85% of their rated ampacity, not less than half as stated in PC 589. Thermocouples were placed at several locations in the wiring methods, including both the highest and lowest elevations. In the conduits they were placed between the conductors, not in contact with the conduit, to accurately capture the temperature of the insulation. For the cables, the jacket was slit and the TCs again placed between the conductors so as to accurately record the temperature on the insulation, which is the critical variable. The wiring methods terminated in wireways at both ends, therefore not open to the atmosphere and limiting potential airflow. This
would greatly reduce airflow, and minimize any "chimney effect." There was no verification provided that the wiring method installation method caused a cooling effect or equalization of temperatures. The wireways used in the UNLV study would not have allowed significant aspiration, and the total interior volume is probably close to that of some electrical boxes, so any aspiration would likely be similar. Solar irradiance was measured and the values were reported to the code-making panel; refer to pages 10 and 12 in the UNLV report. Data was not submitted to demonstrate that a long-running, non-continuous load would result in higher conductor temperatures. Plug connected equipment introduces more resistance to the circuit at the connection points. Continuous loads likely reach a steady state temperature condition, but without data it is not a foregone conclusion that this temperature is lower than that of non-continuous load, as the interruption in current flow when the load is off would allow for some cooling of the conductors. The results of previously submitted studies included results using an air conditioner as the load as requested by the submitter. It is important to note that none of the conductors in the UL studies were energized. As indicated in previously submitted research, the color of the rooftop was not a primary determinant factor, leading to previous code-making panel decisions to include rules applicable to any rooftop color. The UL report indicated that for wiring systems at the 1/2 inch distance above the roof, there was no difference between black and white roof color in terms of wiring system temperatures. The UNLV roof was white, which the UL study indicated was the color allowing additional heating from solar reflection for distances greater than 1/2 inch above the roof. The UNLV wiring systems were located 8 inches above the roof, so this configuration would have captured the maximum temperatures due to roof color. A report was written, and provided to CMP6. As to the submitter's comments regarding the correlating committee task group statement, it was based on work done by scientists experienced in heat flow and electrical ampacity calculations. The work was evaluated and verified by an independent research committee assigned by the NEC Correlating Committee, which was composed of experienced and unbiased electrical and code professionals. Research from other sources supporting the modeling was submitted to the panel. A report was written. The statement and report were submitted to NFPA and the code-making panel. The primary researcher employed on behalf of the Copper Development Association for the UL report was included in the otherwise independent task group. He was an active participant representing the CDA point of view. Representatives of CDA were invited to present to the CC Task Group, as were representatives from other groups that had submitted research to the panel. CDA representatives did in fact present their point of view to the task group. Additionally, both the Copper Development Association and UL were present at the Public Input meetings and were given ample opportunity to argue their point of view. The modeling did not conflict with previously developed data, and the panel is unaware of any UL testimony regarding "wicking" in these deliberations.
(3) Adjustment Factors.

(a) More than Three Current-Carrying Conductors. Where the number of current-carrying conductors in a raceway or cable exceeds three, or where single conductors or multi-conductor cables are installed without maintaining spacing for a continuous length longer than 600 mm (24 in.) and are not installed in raceways, the allowable ampacity of each conductor shall be reduced as shown in Table 310.15(B)(3)(a). Section 310.15(A)(2) exception shall not apply. Each current-carrying conductor of a paralleled set of conductors shall be counted as a current-carrying conductor.

Where conductors of different systems, as provided in 300.3, are installed in a common raceway or cable, the adjustment factors shown in Table 310.15(B)(3)(a) shall apply only to the number of power and lighting conductors (Articles 210, 215, 220, and 230).

Informational Note No. 1: See Annex B for adjustment factors for more than three current-carrying conductors in a raceway or cable with load diversity.

Informational Note No. 2: See 366.23 for adjustment factors for conductors and ampacity for bare copper and aluminum bars in auxiliary gutters and 376.22(B) for adjustment factors for conductors in metal wireways.

(1) Where conductors are installed in cable trays, the provisions of 392.80 shall apply.

(2) Adjustment factors shall not apply to conductors in raceways having a length not exceeding 600 mm (24 in.).

(3) Adjustment factors shall not apply to underground conductors entering or leaving an outdoor trench if those conductors have physical protection in the form of rigid metal conduit, intermediate metal conduit, rigid polyvinyl chloride conduit (PVC), or reinforced thermosetting resin conduit (RTRC) having a length not exceeding 3.05 m (10 ft), and if the number of conductors does not exceed four.

(4) Adjustment factors shall not apply to Type AC cable or to Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. Each cable has not more than three current-carrying conductors.
   c. The conductors are 12 AWG copper.
   d. Not more than 20 current-carrying conductors are installed without maintaining spacing, are stacked, or are supported on "bride rings."

   Exception: A 60 percent adjustment factor shall be applied if the current-carrying conductors in these cables that are stacked or bundled longer than 600 mm (24 in.) without maintaining spacing exceeds 20.

(5) An adjustment factor of 60 percent shall be applied to Type AC cable or Type MC cable under the following conditions:
   a. The cables do not have an overall outer jacket.
   b. The number of current carrying conductors exceeds 20.
   c. The cables are stacked or bundled longer that 600 mm (24 in.) without spacing being maintained.

<sup>1</sup>Number of conductors is the total number of conductors in the raceway or cable, including spare conductors. The count shall be adjusted in accordance with 310.15(B)(5) and (6). The count shall not include conductors that are connected to electrical components that cannot be simultaneously energized.

(b) Raceway Spacing. Spacing between raceways shall be maintained.

(c) Raceways and Cables Exposed to Sunlight on rooftops. Where raceways or cables are exposed to direct sunlight on or above rooftops, raceways or cables shall be installed a minimum distance above the roof to the bottom of the raceway or cable of 23 mm (7 5/16 in.). Where the distance above the roof to the bottom of the raceway is less than 23 mm (7 5/16 in.), a temperature adder of 33°C (60°F) shall be added to the outdoor temperature to determine the applicable ambient temperature for application of the correction factors in Table 310.15(B)(2)(a) or Table 310.15(B)(2)(b).

Exception: Type XHHW-2 insulated conductors shall not be subject to this ampacity adjustment.

Informational Note: One source for the ambient temperatures in various locations is the ASHRAE Handbook — Fundamentals.

Statement of Problem and Substantiation for Public Comment

The exception for XHHW-2 was removed by the panel during deliberations but the vote was not recorded or reported. See PI 2808 First

Statement of Problem and Substantiation for Public Comment

The results by Dr. Shedd and the task group do not contain a problem formulation, do not show how the numbers were developed, and there is also concern about heat transfer coefficients used in the model. The UNLV report contains many errors and miscalculations. The chimney effect from the conduit risers and associated errors should negate the validity this research.

Since the concern is that the temperature of insulation should not rise above critical designed temperatures, direct measurements of temperature on the insulation are most relevant. The effect of flowing current when the conductor is loaded on the heat generated and its effect on the temperature of the insulation would be very important since the conductors will carry current.

In addition to a decrease in strength of conductor insulation with temperature, there will be creep of the insulation material when the temperatures are high since the exposure times are quite long.

The heat transfer coefficient on the outer and inner surfaces of conduits and between the copper and insulation would also influence the results.

We must rely more on experiments than calculations and therefore the results on actual measurements by Underwriters Laboratories are most reliable and should be used in selecting the ampacity and insulation.

Submittal Date: Tue Sep 22 16:54:24 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The submitter's substantiation contained no new information. The submitter did not identify which items in the UNLV reports he believes are errors and miscalculations. No evidence was submitted that any chimney effect was present, or that such effect would negate the validity of the research. The wiring systems in the UNLV tests were terminated in wireways, which would greatly reduce any ‘chimney effect’. Direct measurements on the insulation were taken in the UNLV study and the IAEI study submitted in the 2014 NEC cycle. We agree that the heating effect of flowing current is important, and the information submitted by IAEI, UNLV and the Correlating Committee task group all considered this factor; the CDA reports did not. Heat transfer of various components was considered in the Correlating Committee task group information. The UNLV reports provided data for insulation temperatures and also provided data for current-carrying conductors. The panel has reviewed all studies and other evidence submitted over the last few cycles, and FR 1503 is the result of that review. Multiple studies were submitted showing that energized conductors exposed to direct sunlight on rooftops will not exceed the conductor insulation rating, even without the use of the rooftop adders.
Statement of Problem and Substantiation for Public Comment

This Table was a useful for 36 years. Adding the table back into the NEC will help those in the field. Most electricians in the field do not have calculator and this would be more user friendly. The table was removed and replaced with an 83% calculation and the calculation produces the same numbers as the table. If the table needs to be expanded to include larger services, that can be done too. The table can be added without deleting any of the existing text.

Submittal Date: Fri Sep 25 14:29:40 EDT 2015

Committee Statement
Committee Action: Rejected
Resolution: The panel understands that table 310.15(B)(7) is helpful; however, the panel is also aware that there has been some misunderstanding on how to use this table. Specifically the term “ratings” has been confused to mean “ampacity”. For this reason it was placed in Annex D along with an example on how to determine feeder ratings.
(7) Single-Phase Dwelling Services and Feeders.

For one-family dwellings and the individual dwelling units of two-family and multifamily dwellings, service and feeder conductors supplied by a single-phase, 120/240-volt system shall be permitted to be sized in accordance with 310.15(B)(7)(1) through (4).

Single-phase feeders from a Feeder consisting of 2 ungrounded conductors and the neutral conductor of a 4-wire, 3-phase, 208Y/120 volt system shall be permitted to use 310.15(B)(7)(1) through (4).

(1) For a service rated 100 through 400 amperes, the service conductors supplying the entire load associated with a one-family dwelling, or the service conductors supplying the entire load associated with an individual dwelling unit in a two-family or multifamily dwelling, shall be permitted to have an ampacity not less than 83 percent of the service rating.

(2) For a feeder rated 100 through 400 amperes, the feeder conductors supplying the entire load associated with a one-family dwelling, or the feeder conductors supplying the entire load associated with an individual dwelling unit in a two-family or multifamily dwelling, shall be permitted to have an ampacity not less than 83 percent of the feeder rating.

(3) In no case shall a feeder for an individual dwelling unit be required to have an ampacity greater than that specified in 310.15(B)(7)(1) or (2).

(4) Grounded conductors shall be permitted to be sized smaller than the ungrounded conductors, if the requirements of 220.61 and 230.42 for service conductors or the requirements of 215.2 and 220.61 for feeder conductors are met.

(5) Where correction or adjustment factors are required by 310.15(B)(2) or (3), they shall be permitted to be applied to the ampacity associated with the temperature rating of the conductor.

Informational Note No. 1: The service or feeder ratings addressed by this section are based on the standard ampacity ratings from 240.6(A).

Informational Note No. 2: See Example D7 in Annex D.

Statement of Problem and Substantiation for Public Comment

This language is consistent with the description found in 220.61.

Street Address: 
City: 
State: 
Zip: 
Submittal Date: Wed Sep 23 22:49:17 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-1505-NFPA 70-2015
Statement: The construction of a second paragraph for the 208Y/120-volt system requires the addition of the same limited-dwelling application text in order to remove any ambiguity the addition of the second paragraph might cause.

The addition of the system description text in the second paragraph is to further clarify its exact meaning.

The 208Y/120-volt application is limited to (1) through (3) due to the fact that the neutral of that system is a current-carrying conductor and must always be full sized in accordance with 220.61, and therefore the reduced neutral sizing allowed by (4) can never be applied.

The translation of the last paragraph into list item (5) during the First Revision Terra processing was in error. There is no list item (5).
Single-Phase Dwelling Services and Feeders.

For one-family dwellings and the individual dwelling units of two-family and multifamily dwellings, service and feeder conductors supplied by a single-phase, 120/240-volt system shall be permitted to be sized in accordance with 310.15(B)(7)(1) through (4).

Single-phase feeders from a 208Y/120 volt system shall be permitted to use 310.15(B)(7)(1) through (4).

(1) For a service rated 100 through 400 amperes, the service conductors supplying the entire load associated with a one-family dwelling, or the service conductors supplying the entire load associated with an individual dwelling unit in a two-family or multifamily dwelling, shall be permitted to have an ampacity not less than 83 percent of the service rating.

(2) For a feeder rated 100 through 400 amperes, the feeder conductors supplying the entire load associated with a one-family dwelling, or the feeder conductors supplying the entire load associated with an individual dwelling unit in a two-family or multifamily dwelling, shall be permitted to have an ampacity not less than 83 percent of the feeder rating.

(3) In no case shall a feeder for an individual dwelling unit be required to have an ampacity greater than that specified in 310.15(B)(7)(1) or (2).

(4) Grounded conductors shall be permitted to be sized smaller than the ungrounded conductors, if the requirements of 220.61 and 230.42 for service conductors or the requirements of 215.2 and 220.61 for feeder conductors are met.

(5) Where correction or adjustment factors are required by 310.15(B)(2) or (3), they shall be permitted to be applied to the ampacity associated with the temperature rating of the conductor.

Informational Note No. 1: The service or feeder ratings addressed by this section are based on the standard ampacity ratings from 240.6(A).

Informational Note No. 2: See Example D7 in Annex D.

If no temperature correction or ampacity adjustment factors are required, the following table includes conductor sizes calculated using the requirements in 310.15(B)(7).

Statement of Problem and Substantiation for Public Comment

First I would like to thank the panel for bringing Table 310.15(B)(7) from the 2011 NEC to the 2017 NEC though it is in the Annex with the First Revision. The issue is that the NEC should be user friendly. With the code language in 310.15(B)(7) and the table in the back does not help inspectors, electricians, etc. We need to keep it simple and have all the tools together. The table works fine without going through an 83% calculation. In addition the Annex is not enforceable, however 310.15(B)(7) is. At a glance at the table conductors can be sized without referring to the Annex. As mentors of the code we have knowledge of the what the Annex is however many new users and some installers don't understand the annex and are intimidated to go there. Chapters 1-4 are their meat and potatoes. They believe the Annex is for engineers. Let's keep it simple.

Please move the following wording and the table from the Annex D to 310.15(B)(7) for the 2017 NEC.

If no temperature correction or ampacity adjustment factors are required, the following table includes conductor sizes calculated using the requirements in 310.15(B)(7).

**Committee Statement**

- **Committee Action:** Rejected
- **Resolution:**
The panel understands that table 310.15(B)(7) is helpful; however, the panel is also aware that there has been some misunderstanding on how to use this table. Specifically the term “ratings” has been confused to mean “ampacity”. For this reason it was placed in Annex D along with an example on how to determine feeder ratings.
310.104 Conductor Constructions and Applications.
Insulated conductors shall comply with the applicable provisions of Table 310.104(A) through Table 310.104(E).

**Informational Note 1**: Thermoplastic insulation may stiffen at temperatures lower than -10°C (+14°F). Thermoplastic insulation may also be deformed at normal temperatures where subjected to pressure, such as at points of support.

**Informational Note 2**: The requirements associated with the term flame retardant for each type of insulation are contained within the listing standard for the relevant insulation. Often, one method of determining that the insulation is flame retardant is by testing the insulation, or the cable, to the VW-1 (Vertical Wire) test in ANSI/UL 1581-2011, Reference Standard for Electrical Wires, Cables and Flexible Cords.

1 Conductors can be rated up to 1000 V if listed and marked.
2 Some insulations do not require an outer covering.
3 Where design conditions require maximum conductor operating temperatures above 90°C (194°F).
4 For signaling circuits permitting 300-volt insulation.
5 For ampacity limitation, see 340.80.
6 Includes integral jacket.
7 Insulation thickness shall be permitted to be 2.03 mm (80 mils) for listed Type USE conductors that have been subjected to special investigations. The nonmetallic covering over individual rubber-covered conductors of aluminum-sheathed cable and of lead-sheathed or multiconductor cable shall not be required to be flame retardant. For Type MC cable, see 330.104. For nonmetallic-sheathed cable, see Article 334, Part III. For Type UF cable, see Article 340, Part III.

*Under a common overall covering such as a jacket, sheath, or armor.
**100 Percent Insulation Level.** Cables in this category shall be permitted to be applied where the system is provided with relay protection such that ground faults will be cleared as rapidly as possible but, in any case, within 1 minute. While these cables are applicable to the great majority of cable installations that are on grounded systems, they shall be permitted to be used also on other systems for which the application of cables is acceptable, provided the above clearing requirements are met in completely de-energizing the faulted section.

**133 Percent Insulation Level.** This insulation level corresponds to that formerly designated for ungrounded systems. Cables in this category shall be permitted to be applied in situations where the clearing time requirements of the 100 percent level category cannot be met and yet there is adequate assurance that the faulted section will be de-energized in a time not exceeding 1 hour. Also, they shall be permitted to be used in 100 percent insulation level applications where additional insulation is desirable.

**173 Percent Insulation Level.** Cables in this category shall be permitted to be applied under all of the following conditions:

1. In industrial establishments where the conditions of maintenance and supervision ensure that only qualified persons service the installation
2. Where the fault clearing time requirements of the 133 percent level category cannot be met
3. Where an orderly shutdown is essential to protect equipment and personnel
4. There is adequate assurance that the faulted section will be de-energized in an orderly shutdown

Also, cables with this insulation thickness shall be permitted to be used in 100 or 133 percent insulation level applications where additional insulation strength is desirable.

### Statement of Problem and Substantiation for Public Comment

The panel stated that the VW-1 test is not always required and therefore this public comment adds a sentence that states that fact. That added sentence clarifies that the listing standard contains the fire test. However, in many (if not most) cases the appropriate test is the VW-1 test. More importantly, the term "flame retardant" as such is not an appropriate term without clarification because the term flame retardant simply refers to the additives that are used to improve fire performance, unless the fire performance is clarified.

### Submitter Information Verification

**Submitter Full Name:** Marcelo Hirschler  
**Organization:** GBH International  
**Street Address:**  
**City:**  
**State:**  
**Zip:**  
**Submittal Date:** Tue Sep 22 15:19:02 EDT 2015

### Committee Statement

**Committee Action:** Rejected  
**Resolution:** The submitter states in his substantiation that “in many (if not most) cases the appropriate test is the VW-1 test.” However, this is not true for the products listed in 310.104(A). For most of these products VW-1 is not the required flame test. Therefore, the informational note may be misleading. The products standards contain the information required for flame testing.
Public Comment No. 1790-NFPA 70-2015 [Section No. 312.1]

312.1 Scope.
This article covers the installation and construction specifications of cabinets, cutout boxes, and meter socket enclosures. It does not apply to equipment operating at over 1000 volts, except as specifically referenced elsewhere in the Code.

Statement of Problem and Substantiation for Public Comment
The Correlating Committee directs the panel to give further consideration to the comments expressed in voting on FR 2401.

State:
Zip:
Submittal Date: Mon Sep 28 15:55:25 EDT 2015

Committee Statement
Committee Action: Rejected
Resolution: CMP 9 reviewed the record and the First Draft text. The Panel retains the First Draft text. The second sentence in 312.1 addressing the voltage limitation applicable to this article was added exactly as written in the first draft report. The statement reported in the first revision report was not the one voted by the panel. The correct statement, inserted here to clarify the record, is as follows: "CMP 9 concludes that the equipment addressed in Article 312 is not generally designed to exceed the voltage parameters in Article 408 and has applied comparable language from 408.1 to address this topic. CMP 9 recognizes that the Correlating Committee has jurisdiction over scope provisions and recommends this revision accordingly."
Statement of Problem and Substantiation for Public Comment

The addition of 312.8 (B) would limit the installation of devices and equipment to only those enclosures that they were specifically assessed within by qualified test labs. Due to the large number of enclosures currently on the market, and the even greater number of discontinued enclosures already in the field, this requirement is so burdensome as to be completely impractical, and would result in the elimination of any 3rdparty devices from the market.

These 3rdparty devices have proven to be the only viable way of addressing the current install base of enclosures across the US.

3rdparty devices fill a critical role in the growth of renewable energy by providing the necessary sensor data to optimally manage a home’s participation on the grid. Lack of such information will hinder the deployment of technologies such as solar, battery storage, microgrid and demand response which are key to achieving a stable, sustainable grid.

In their statement regarding this proposed change, CMP9 references an earlier proposal to allow the installation of utilization equipment which was rejected in the 2011 cycle. We recognize that the wide variety of existing devices classified as ‘utilization equipment’ and not designed for installation inside enclosures could result in obstruction and hazard. However, we propose that a device specifically designed for installation within any listed enclosures and evaluated by qualified test lab for installation inside any listed enclosures can be safely installed.

In order to provide clarity, we suggest the NEC specifies that a device may only be installed inside an enclosure if it is listed and approved for installation inside any listed enclosure by a qualified test lab. The installation of the device must not force any components (e.g. splices, taps, conductors) out of compliance with the NEC.

To address CMP9's concerns about obstructions in the enclosure, we propose a limit on the amount of space that can be occupied by the device, splices, taps and conductors in any crosssectional area. Evaluation of this limit should should be performed by the Inspector during the standard inspection process. A field evaluation would not be practical as no network of evaluators exists that could handle the required volume.

Public Comment No. 376-NFPA 70-2015 [Section No. 312.5(C)]

(C) Cables.
Where cable is used, each cable shall be secured to the cabinet, cutout box, or meter socket enclosure.

Exception: Cables with entirely nonmetallic sheaths shall be permitted to enter the top of a surface-mounted enclosure through one or more nonflexible raceways not less than 450 mm (18 in.) and not more than 3.0 m (10 ft) in length, provided all of the following conditions are met:

(a) Each cable is fastened within 300 mm (12 in.), measured along the sheath, of the outer end of the raceway.
(b) The raceway extends directly above the enclosure and does not penetrate a structural ceiling.
(c) A fitting is provided on each end of the raceway to protect the cable(s) from abrasion and the fittings remain accessible after installation.
(d) The raceway is sealed or plugged at the outer end using approved means so as to prevent access to the enclosure through the raceway.
(e) The cable sheath is continuous through the raceway and extends into the enclosure beyond the fitting not less than 6 mm (0.25 in.).
(f) The raceway is fastened at its outer end and at other points in accordance with the applicable article.
(g) Where installed as conduit or tubing, the cable fill does not exceed the amount that would be permitted for complete conduit or tubing systems by Table 1 of Chapter 9 of this Code and all applicable notes there to. Note 2 to Chapter 9, Table 1, Note 2: Tables does not apply to this condition.

Informational Note: See Table 1 in Chapter 9, including Note 9, for allowable cable fill in circular raceways. See 310.15(B)(3) (a) for required ampacity reductions for multiple cables installed in a common raceway.

Statement of Problem and Substantiation for Public Comment
The notes in Chapter 9, do not apply to Table 1, they apply to the tables contained in Chapter 9.

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-2402-NFPA 70-2015
Statement: CMP 9 agrees with the concept that the referenced notes apply to the tables generally, and not just to Table 1. This wording accomplishes the objectives of the submitter, but flows better editorially.
Public Comment No. 1040-NFPA 70-2015 [ Section No. 312.6(A) ]

(A) Width of Wiring Gutters.
Conductors shall not be deflected within a cabinet or cutout box unless a gutter having a width in accordance with Table 312.6(A) is provided. Conductors in parallel in accordance with 310.10(H) shall be judged on the basis of the number of conductors in parallel.

Note: Bending space at terminals shall be measured in a straight line from the end of the lug or wire connector (in the direction that the wire leaves the terminal) to the wall, barrier, or obstruction.

2. This column shall be permitted to be used to determine the required minimum wire-bending space for compact stranded aluminum conductors in sizes up to 1000 kcmil and manufactured using AA-8000 series electrical grade aluminum alloy conductor material in accordance with 310.106(B). The minimum width of the wire gutter space shall be determined using the all other conductors value in this table.

Statement of Problem and Substantiation for Public Comment

The NEMA wire bending study to validate the inclusion of AA-8000 AL wire bending allowances to this table is well underway. The results will be available by the second draft meeting.

Committee: Rejected but see related SR
Action:
Resolution: SR-2403-NFPA 70-2015
Statement: The fact-finding study sought by the panel members who objected to the action taken on FR #2435 that inserted this material into Table 312.6(A) has been completed and, together with additional information, has been reviewed by the panel. CMP 9 has some concerns relative to the fact that the study set-up did not involve actual electrical enclosures. On the other hand, Table 314.6(A), unlike the (B) table, generally covers bends that are made outside the enclosure and then set into place. In addition, there is substantial information available in the public domain relative to the more forgiving characteristics of the aluminum now being used for conductors. After reviewing all information, CMP 9 concludes that the revised dimensions for aluminum conductors are consistent with minimum safety standards and provide a useful correlation with comparable material in Table 312.6(B). The two tables cover differing facets of the same technical issues.

The Panel also edited the note numbering at the bottom of the table to be consistent with Table 312.6(B).
Public Comment No. 1046-NFPA 70-2015 [Section No. 312.8]

(A) Switch and Overcurrent Device Enclosures.

312.8 Switch and Overcurrent Device Enclosures.

The wiring space within enclosures for switches and overcurrent devices shall be permitted for other wiring and equipment only as provided in (A) and (B).

with Splices, Taps, and Feed-Through Conductors.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for conductors feeding through, spliced, or tapping off to other enclosures, switches, or overcurrent devices where all of the following conditions are met:

(1) The total of all conductors installed at any cross section of the wiring space does not exceed 40 percent of the cross-sectional area of that space.

(2) The total area of all conductors, splices, taps, devices, and equipment installed at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

(3) A warning label complying with 110.21(B) is applied to the enclosure that identifies the closest disconnecting means for any feed-through conductors.

(B) Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

(1) The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit evaluated for field installation in the specific equipment.

(2) The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

As originally worded, this proposal appears to prohibit the field installation of truly an infinite number of flange and/or surface mounted devices whereby terminations must protrude into the interior panel enclosure space. Specific to electrical wiring devices, potentially affected products could include manual controllers, flanged straight blade and locking inlets and outlets, cam-type panel mount devices and IEC 309 pin & sleeve receptacles. In each case, the device terminations protrude inside of the enclosure if they are panel mounted on the exterior of the panelboard or motor control center. These are not atypical applications; similarly, it places a completely unreasonable burden on the manufacturers of these devices to ensure that replacement kits or the flange/surface mounted devices themselves are listed to the (once again) infinite number of panelboard and/or motor control center products offered by industry.

The request here is to revert to the existing 2014 NFPA 70 text for NEC® 312.8. Thank you.

Committee Statement

Committee: Rejected but see related SR
Action: 
**Resolution:** SR-2401-NFPA 70-2015

**Statement:** CMP 9 agrees that the initial revision was excessively broad and carried unintended consequences. The inspection community does have, and has routinely applied, the tools required to police other intrusions into the wiring gutters of this equipment in the event of a problem. This action at this stage, which includes making correlating changes in the parent language, limits the additional specific coverage in this cycle to power monitoring equipment. This is now covered by a comparatively new UL Outline of Investigation (UL 2808, Guide Card XOBA, with markings that describe the CT equipment and the energy monitoring function, such as “energy-monitoring CT”).

CMP 9 is retaining the two-part structure of this section so that the new Part B can be easily expanded in the future as may be judged necessary based on subsequent field experience. The final result also includes some of the language from Comment 1178, which was informed by the UL standards activity.
Public Comment No. 1054-NFPA 70-2015 [Section No. 312.8]

(A) Switch and Overcurrent Device Enclosures.

The wiring space within enclosures for switches and overcurrent devices shall be permitted for other wiring and equipment only as provided in (A) and (B).

Enclosures with Splices, Taps, and Feed-Through Conductors, and Power Monitoring Equipment.

The wiring space of within enclosures for switches or overcurrent devices shall be permitted for listed power monitoring equipment, conductors feeding through, spliced, or tapping off to other enclosures, switches, or overcurrent devices where all of the following conditions are met:

1. The total of all conductors installed at any cross section of the wiring space does not exceed 40 percent of the cross-sectional area of that space.

2. The total area of all conductors, splices, taps, devices and equipment installed and listed power monitoring equipment installed at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

3. A warning label complying with 110.21(B) is applied to the enclosure that identifies the closest disconnecting means for any feed-through conductors.

(B) Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

1. The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit evaluated for field installation in the specific equipment.

2. The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

The inclusion of devices and equipment is too broad and verification that all safety aspects were addressed would be very difficult. Power monitoring equipment could be installed using the general rules of this section without impacting the performance of the overcurrent devices installed in the enclosure.

The final result also includes some of the language from Comment 1178, which was informed by the UL standards activity.
Switch and Overcurrent Device Enclosures.

The wiring space within enclosures for switches and overcurrent devices shall be permitted for other wiring and equipment only as provided in (A) and (B).

(A) Splices, Taps, and Feed-Through Conductors.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for conductors feeding through, spliced, or tapping off to other enclosures, switches, or overcurrent devices where all of the following conditions are met:

1. The total of all conductors installed at any cross section of the wiring space does not exceed 40 percent of the cross-sectional area of that space.
2. The total area of all conductors, splices, taps, devices and equipment installed at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.
3. A warning label complying with 110.21(B) is applied to the enclosure that identifies the closest disconnecting means for any feed-through conductors.

(B) Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

1. The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit evaluated for field installation in the specific equipment switch or overcurrent device enclosures.
2. The total area of all conductors, splices, taps, devices, and equipment installed at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

As noted in the substantiation to FR 2404, this revision is intended to limit the inclusion of devices and equipment in a wiring space to those that are identified as field installable accessories as part of the listed equipment, or as a listed kit evaluated for field installation in the specific equipment. The phrase "listed kit evaluated for field installation in the specific equipment" may be interpreted as requiring a kit to include an itemized list of the "specific equipment" with which the kit is compatible. Additionally, this equipment may be provided in designs which are not considered a "kit". As the original submitter of the Public Input which generated the First Revision, I am providing a Public Comment which is intended to clarify a portion of this requirement in a way that is consistent with my original intent. The substantive change to the wording in 312.8(B)(1) ("...the device or equipment is listed as being evaluated for field installation in switch or overcurrent device enclosures.") would meet the original intent, which is to ensure the added device or equipment is listed equipment that has been evaluated for field installation in the application. The UL category for "Energy-Monitoring Current Transformers" (XOBA) is an example of equipment that would satisfy this requirement.

The final result also includes some of the language from Comment 1178, which was informed by the UL standards activity.
312.8 Switch and Overcurrent Device Enclosures.

The wiring space within enclosures for switches and overcurrent devices shall be permitted for other wiring and equipment only as provided in (A) and (B).

(A) Splices, Taps, and Feed-Through Conductors.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for conductors feeding through, spliced, or tapping off to other enclosures, switches, or overcurrent devices where all of the following conditions are met:

(1) The total area of all conductors installed at any cross section of the wiring space does not exceed 40 percent of the cross-sectional area of that space.

(2) The total area of all conductors, splices, taps, devices and equipment installed at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

(3) A warning label complying with 110.21(B) is applied to the enclosure that identifies the closest disconnecting means for any feed-through conductors.

(B) Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted to be occupied by devices and equipment where all of the following conditions are met:

(1) The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit evaluated for field installation in the specific equipment switch and overcurrent device enclosures, and

(2) The total area of all conductors, splices, taps, devices, and equipment installed at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

As originally worded, it appears this proposal would prohibit the installation of current transformers or meters for energy monitoring in any switch and overcurrent device enclosures unless every possible current transformer or meter was evaluated and listed for use in every possible enclosure. If this interpretation is correct, it puts a financially insurmountable burden on the submetering industry. The industry as a whole has an excellent safety record with respect to recognized and listed metering devices placed within switch and overcurrent device enclosures. The success of such applications over multiple decades of use, together with the originally proposed wording for [Part B] seems, in practice, to effectively limit devices permitted within switch and overcurrent device enclosures to only those made by the enclosure manufacturer and could thus be perceived within the context of restraint of trade as anti-competitive.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-2401-NFPA 70-2015
Statement: CMP 9 agrees that the initial revision was excessively broad and carried unintended consequences. The inspection community does have, and has routinely applied, the tools required to police other intrusions into the wiring gutters of this equipment in the event of a problem. This action at this stage, which includes making correlating changes in the parent language, limits the additional specific coverage in this cycle to power monitoring equipment. This is now covered by a comparatively new UL Outline of Investigation (UL 2808, Guide Card XOBA, with markings that describe the CT equipment and the energy monitoring function, such as “energy-monitoring CT”).
CMP 9 is retaining the two-part structure of this section so that the new Part B can be easily expanded in the future as may be judged necessary based on subsequent field experience. The final result also includes some of the language from Comment 1178, which was informed by the UL standards activity.
Public Comment No. 1182-NFPA 70-2015 [Section No. 312.8]

312.8 Switch and Overcurrent Device Enclosures.

The wiring space within enclosures for switches and overcurrent devices shall be permitted for other wiring and equipment only as provided in (A) and (B).

(A) Splices, Taps, and Feed-Through Conductors.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for conductors feeding through, spliced, or tapping off to other enclosures, switches, or overcurrent devices where all of the following conditions are met:

1. The total area of all conductors installed at any cross section of the wiring space does not exceed 40 percent of the cross-sectional area of that space.
2. The total area of all conductors, splices, taps, devices and equipment installed at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.
3. A warning label complying with 110.21(B) is applied to the enclosure that identifies the closest disconnecting means for any feed-through conductors.

(B) Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted to be occupied by devices and equipment where all of the following conditions are met:

1. The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit evaluated for field installation in the specific equipment switch and overcurrent device enclosures.
2. The total area of all conductors, splices, taps, devices, and equipment installed at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

As originally worded, it appears this proposal would prohibit the installation of current transformers or meters for energy monitoring in any switch and overcurrent device enclosures unless every possible current transformer or meter was evaluated and listed for use in every possible enclosure. If this interpretation is correct, it puts a financially insurmountable burden on the submetering industry. The industry as a whole has an excellent safety record with respect to recognized and listed metering devices placed within switch and overcurrent device enclosures. The success of such applications over multiple decades of use, together with the originally proposed wording for [Part B] seems, in practice, to effectively limit devices permitted within switch and overcurrent device enclosures to only those made by the enclosure manufacturer and could thus be perceived within the context of restraint of trade.

(A) - Switch and Overcurrent Device Enclosures.

The wiring space within enclosures for switches and overcurrent devices shall be permitted for other wiring and equipment only as provided in (A) and (B).

with Splices, Taps, and Feed-Through Conductors.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for conductors feeding through, spliced, or tapping off to other enclosures, switches, or overcurrent devices where all of the following conditions are met:

1. The total of all conductors installed at any cross section of the wiring space does not exceed 40 percent of the cross-sectional area of that space.

2. The total area of all conductors, splices, taps, devices and equipment installed at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

3. A warning label complying with 110.21(B) is applied to the enclosure that identifies the closest disconnecting means for any feed-through conductors.

(B) - Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

1. The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit evaluated for field installation in the specific equipment

2. The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

This FR should be revised to delete the new 312.8(B) and revert back to the NEC 2014 language with only the addition of "devices and equipment".

The original PI3091 cited "proliferation of devices and equipment" as substantiation for the change, however, the PI did not include any data that can be substantiated as safety concerns and how the PI would address those concerns. This proposal would effectively prohibit the installation of LISTED current transformers or meters for energy monitoring in any switch and overcurrent device enclosures, unless every possible current transformer or meter was evaluated and listed for use in every possible enclosure in their every possible internal, both factory and field installed, configurations. This will put a financially insurmountable burden and virtually impossible requirement on, but not limited to, the submetering industry, and to effectively limit all devices within switch and overcurrent device enclosures to only those made by the enclosure manufacturer and could thus be perceived within the context of restraint of trade. Additionally, this proposal will slow the introduction of new enclosure models as well as prohibiting entry of new enclosure manufacturers/suppliers, because all new enclosures will lack products "listed" for use with/within them. Bust most of all, the submetering industry as a whole has had an excellent safety record with respect to recognized and listed metering devices placed within switch and overcurrent device enclosures, and the original PI had provided no evidence to prove otherwise.

It seems that if the committee was concerned with maintaining adequate wiring space, the solution would be to include "devices and equipment" as part of the cross section calculations, as proposed in 312.8(A)(@) of FR2404.

312.8 Switch and Overcurrent Device Enclosures with Splices, Taps, Feed-Through Conductors, and Power Monitoring or measuring Equipment.

The wiring space within enclosures for switches and overcurrent devices shall be permitted for other wiring and equipment only as provided in (A) and (B), listed power monitoring or measuring equipment, conductors feeding through, spliced, or tapping off to other enclosures, switches, or overcurrent devices where all of the following conditions are met.

(A) Splices, Taps, and Feed-Through Conductors.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for listed power monitoring or measuring equipment, conductors feeding through, spliced, or tapping off to other enclosures, switches, or overcurrent devices where all of the following conditions are met:

1. The total of all conductors installed at any cross section of the wiring space does not exceed 40 percent of the cross-sectional area of that space.

2. The total area of all conductors, splices, taps, devices and equipment installed at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

3. A warning label complying with 110.21(B) is applied to the enclosure that identifies the closest disconnecting means for any feed-through conductors.

(B) Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

1. The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit evaluated for field installation in the specific equipment.

2. The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

Section 312.8 in the NEC-2014 permits Splices, Taps, and Feed-Through Conductors in the wiring space. The installation of listed monitoring or measuring equipment in industrial buildings, multiuse commercial, university campus buildings and Government facilities is vital to determine their energy usage and develop programs to reduce their energy consumption and carbon footprint. Components of the listed monitoring or measuring equipment may need to be in the wire bending space of the equipment that is already installed to accomplish this. The current section does not address this equipment and does not provide any guidance to the AHJ. With no guidance it may prevent the installation of equipment needed to meet this important emerging need or lead to unsafe installation.

FR 2404 as written can be confusing because of the use of devices and equipment. It is unclear if the requirement applies to all equipment in the enclosure and how one would distinguish the wiring space from the equipment space for some types of enclosures, particularly those used for industrial control equipment.

This proposal specifically addresses energy management or measuring equipment that is installed in the wiring space. It is the addition of this equipment that is the issue at present and is what the FR should address. Adding the requirement for Listed equipment and applying the same area limitation will enhance the safety of the installation. The language of the proposal also establishes enforceable guidelines for the AHJ through the Listing and specific area requirements.

This proposal also supports the important trend of energy measurement enabling conservation and reduction of carbon footprint. Many municipalities are in process of or are considering legislating energy measurement. The code should be aligned with this emerging need while providing the guidance for safe installations.

Public Comment No. 1700-NFPA 70-2015 [Section No. 312.8]

312.8 Switch and Overcurrent Device Enclosures.

The wiring space within enclosures for switches and overcurrent devices shall be permitted for other wiring and equipment only as provided in (A) and (B).

(A) Splices, Taps, and Feed-Through Conductors.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for conductors feeding through, spliced, or tapping off to other enclosures, switches, or overcurrent devices where all of the following conditions are met:

(1) The total of all conductors installed at any cross section of the wiring space does not exceed 40 percent of the cross-sectional area of that space.

(2) The total area of all conductors, splices, taps, devices and equipment installed at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

(3) A warning label complying with 110.21(B) is applied to the enclosure that identifies the closest disconnecting means for any feed-through conductors.

(B) Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

(1) The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit listed and evaluated for field installation in the specific equipment installation within any listed enclosure.

(2) The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

The addition of 312.8 (B) would limit the installation of devices and equipment to only those enclosures that they were specifically assessed within by qualified test labs. Due to the large number of enclosures currently on the market, and the even greater number of discontinued enclosures already in the field, this requirement is so burdensome as to be completely impractical, and would result in the elimination of any 3rd party devices from the market. These 3rd party devices have proven to be the only viable way of addressing the current install base of enclosures across the US.

3rd party devices fill a critical role in the growth of renewable energy by providing the necessary sensor data to optimally manage a home’s participation on the grid. Lack of such information will hinder the deployment of technologies such as solar, battery storage, microgrid and demand response which are key to achieving a stable, sustainable grid.

In their statement regarding this proposed change, CMP9 references an earlier proposal to allow the installation of utilization equipment which was rejected in the 2011 cycle. We recognize that the wide variety of existing devices classified as ‘utilization equipment’ and not designed for installation inside enclosures could result in obstruction and hazard. However, we propose that a device specifically designed for installation within any listed enclosures and evaluated by qualified test lab for installation inside any listed enclosures can be safely installed.

In order to provide clarity, we suggest the NEC specifies that a device may only be installed inside an enclosure if it is listed and approved for installation inside any listed enclosure by a qualified test lab. The installation of the device must not force any components (e.g. splices, taps, conductors) out of compliance with the NEC.

To address CMP9’s concerns about obstructions in the enclosure, we propose a limit on the amount of space that can be occupied by the device, splices, taps and conductors in any cross-sectional area. Evaluation of this limit should should be performed by the Inspector during the standard inspection process. A field evaluation would not be practical as no network of evaluators exists that could handle the required volume.

(2) The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

As proposed, this First Revision FR 2404 (and the Public Input PI 3091) revision to NEC® 312.8 is neither enforceable as worded, practicable in application, nor sufficiently justified to warrant these changes. Revert to existing 2014 text for NEC® 312.8.

FIELD-INSTALLABLE ACCESSORIES AS PART OF LISTED EQUIPMENT and LISTED KITS

Public Input PI 3091 that served as the basis for First Revision FR 2404 rationalized these changes: “There is a proliferation of devices and equipment intended by non-OEM’s to be installed in enclosures containing PANELBOARDS.” Article 408 covers panelboards; Article 312, by contrast, covers CABINETS. These are typically EMPTY enclosures that are “populated” by equipment that the electrician provides at the installation.

Firstly, NEC® Article 312 has no requirement that cabinets, as defined in Article 100, be listed. Indeed, such cabinets presently may be field-fabricated for the installation. Yet NEC® 312.8 as revised by FR 2404 mandates that these devices and equipment be either LISTED accessories or LISTED kits in relation to these enclosures.

Even those electrical enclosures that are listed do so in accordance with UL Standard UL 50. These are empty enclosures, typically listed by ENCLOSURE manufacturers who do NOT make any of the devices or equipment that go inside or are attached to such UL 50 enclosures. Those devices and equipment are manufactured by manufacturers with specialization and competence to manufacture such devices and equipment.

As such, there has ALWAYS been a “proliferation” of devices and equipment made by OTHER THAN the cabinet enclosure manufacturers. If there are specific hazards for panelboards, identify exactly what they are and address them in Article 408, not in Article 312. To now require that manufacturers of such devices and equipment get them listed for EACH and EVERY enclosure manufacturer’s cabinets is fundamentally unachievable. Certainly, the enclosure manufacturers do not have the resources or desire to list as an accessory or kits EACH and EVERY device and equipment that could potentially go in or on those cabinets. As proposed, the 312.8(B)(1) wording of PI 3091 and FR 2404 is not remotely achievable, especially when cabinets onto themselves are not required by Article 312 to be listed.

ENCLOSURE GEOMETRY

NEC® 312.6(A) and Table 312.6(A) establish the width of passages for conductors called wiring gutters. The width requirement is
based upon the size of the conductors in PARALLEL. As such, knowing the measureable width and depth of gutters, the cross-sectional AREA can be calculated. Percentages of conductor fill can be enforced. Any intrusion of a device or equipment in an enclosure effectively re-establishes new (reduced) gutter widths for conductor to pass around the intrusion. Those new (reduced) gutters (conductor passages) still must comply with existing Table 312.6(A). Consequently, those existing Table 312.6(A) gutter widths can still be enforced.

By contrast, the 312.8(B)(2) wording of PI 3091 and FR 2404 is not necessarily looking at where the CONDUCTORS are in PARALLEL but rather where the devices and equipment intrude into the VOLUME of the cabinet enclosure (where conductors are not necessarily running in parallel) and attempt to apply an UNORIENTED cross-section AREA restriction upon a VOLUME. Worded as it is, by whatever the issue unexplained by PI3091 may or may not be, how would this requirement ever be interpreted consistently for enforcement?

FR2404 seems to be a solution looking for a problem to solve.

Public Comment No. 507-NFPA 70-2015 [Section No. 312.8(A)]

(A) Splices, Taps, and Feed-Through Conductors.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for conductors feeding through, spliced, or tapping off to other enclosures, switches, or overcurrent devices where all of the following conditions are met:

1. Any and all feed through conductors are returning from the load served by the switch or overcurrent device and are fully deenergized by the operation of the switch or overcurrent device whose enclosure they pass through.
2. The total of all conductors installed at any cross section of the wiring space does not exceed 40 percent of the cross-sectional area of that space.
3. The total area of all conductors, splices, taps, devices and equipment installed at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.
4. A warning label complying with 110.21(B) is applied to the enclosure that identifies the closest disconnecting means for any feed-through conductors.

Statement of Problem and Substantiation for Public Comment

The Code's present allowance for conductors to pass through an enclosure for a disconnect or overcurrent device without being switched by that device is potentially perilous in practice. While the Code does provide three requirements that must be met, all three rely on the installing electrician's compliance and the AHJ's observation for a safe installation.

The first two requirements dealing with conductor cross-section/fill rely on the electrician's judgment at the time of the installation. It's reasonable to assume that there are countless installations where the electrician has added "just one more wire" if he or she cared at all about fill and the disconnect is not actually to code due to excess fill.

The third requirement for a warning label again relies on the electrician to make the effort to install said label. In installations where the disconnect is subject the OSHA or other regulatory oversight, there's a decent to good chance that this label will be installed. In many other installations, it's doubtful that the effort would be taken and even more doubtful that the label would comply with 110.21(B) as required in the 2014 edition of the Code.

Another matter that the code does not address in 312.8 is the potential for damage to any feed through conductors in the event of a fault or arcing within the enclosure.

Making the revision as I have proposed would help to eliminate undue risk to service personnel operating on the equipment side of a disconnect or overcurrent device. In most cases, it would also eliminate the opportunity for an electrician to make a field judgment on whether the feed-through conductors and any splices or taps installed in the enclosure actually fall within the allowable occupation of the available cross section in the enclosure. While additional raceways would be required as a result of this revision, the increase in cost would be offset by a substantial increase in safety. Additionally, should any conduits be routed around a disconnect, it would serve as a visual warning to a service technician that power may have an additional path into the equipment he or she is working on.

For what it is worth, this proposed revision was proposed as a result of a service technician's near miss on a project I'm working on now. A disconnect was installed with feed-through conductors leading up to a unit heater. The equipment that the disconnect will be disconnecting has not been installed yet. A technician arrived on site to commission the heater that was fed through the only conduit leaving the disconnect switch. The technician threw the disconnect and locked it in the open position. Had he not taken the moment to double check for voltage at the heater he was servicing, there is a good chance he would have at least been shocked and would have fallen off of the ladder he was on and onto equipment below him. In short, a situation created by the Code-compliant omission of an enclosure below the disconnect and a few extra feet of conduit from that enclosure to the load could easily have resulted in a lost time injury or even a fatality.

<td><strong>Resolution:</strong> This comment is not submitted on any observable public input; none was submitted by anyone on this material, and the one cited as a &quot;Related Item&quot; (FR-1) is an amendment to 90.2(A) that has no bearing on the subject of this comment. It is therefore completely new material and it cannot be acted on. CMP 9 also declines to &quot;REJECT BUT HOLD&quot; this comment because there seems to be no likelihood that it would ever be acceptable. The substantiation points to a problem that would never have occurred had the relevant code provisions been applied and enforced. The confusion with respect to the function of the disconnect switch that was locked open would never have occurred had the disconnect function been marked on the switch as required by 110.22(A). The substantiation also points to a perceived lack of appropriate inspections in the applicable jurisdiction. The NEC should never be expected to address jurisdictional failures in this regard. The North American electrical safety system relies on qualified, disinterested third-party inspection as one of three essential components for electrically safe installations. Indeed, the logo of the International Association of Electrical Inspectors describes the organization as the keystone of the electrical industry, for good reason. The other two components of the safety system, namely, a consensus based installation standard (the NEC) and appropriate product standards, were never intended to function without appropriate electrical inspections. The statement in the opening paragraph of the substantiation, that safety in the cited example relies on &quot;the AHJ’s observation for a safe installation,&quot; is quite true, and it unintentionally discredits the remainder of the argument.</td>

Public Comment No. 1077-NFPA 70-2015 [Section No. 312.8(B)]

(B) Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

1. The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit evaluated for field installation in the specific equipment.

2. The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

The safety risks associated with the installation of devices in the wiring space of enclosures for switches or overcurrent devices are best addressed by the listing of the devices in question. The proposed edit allows for devices to be evaluated in a type of enclosure, rather than each individual make/model. This, along with the provision to limit the cross-sectional area, will satisfy the intent of the proposal while allowing for devices to be installed in existing installations, where individual evaluations would be impractical or impossible.

The proposal as written would have unintended, far-reaching implications, and affect the already widespread use of devices and current transformers in energy management and monitoring systems.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-2401-NFPA 70-2015
Statement: CMP 9 agrees that the initial revision was excessively broad and carried unintended consequences. The inspection community does have, and has routinely applied, the tools required to police other intrusions into the wiring gutters of this equipment in the event of a problem. This action at this stage, which includes making correlating changes in the parent language, limits the additional specific coverage in this cycle to power monitoring equipment. This is now covered by a comparatively new UL Outline of Investigation (UL 2808, Guide Card XOBA, with markings that describe the CT equipment and the energy monitoring function, such as “energy-monitoring CT”).

CMP 9 is retaining the two-part structure of this section so that the new Part B can be easily expanded in the future as may be judged necessary based on subsequent field experience. The final result also includes some of the language from Comment 1178, which was informed by the UL standards activity.
Public Comment No. 1118-NFPA 70-2015 [Section No. 312.8(B)]

(B) Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

(1) The device or equipment is identified as a field-installable accessory as part of the listed equipment, or is a listed kit and evaluated for field installation in the specific equipment installation inside any listed enclosure.

(2) The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

The addition of 312.8 (B) would limit the installation of devices and equipment to only those enclosures that they were specifically assessed within by qualified test labs. Due to the large number of enclosures currently on the market, and the even greater number of discontinued enclosures already in the field, this requirement is so burdensome as to be completely impractical, and would result in the elimination of any 3rd-party devices from the market. These 3rd-party devices have proven to be the only viable way of addressing the current install base of enclosures across the US.

3rd-party devices fill a critical role in the growth of renewable energy by providing the necessary sensor data to optimally manage a home’s participation on the grid. Lack of such information will hinder the deployment of technologies such as solar, battery storage, micro-grid and demand response which are key to achieving a stable, sustainable grid.

In their statement regarding this proposed change, CMP9 references an earlier proposal to allow the installation of utilization equipment which was rejected in the 2011 cycle. We recognize that the wide variety of existing devices classified as ‘utilization equipment’ and not designed for installation inside enclosures could result in obstruction and hazard. However, we propose that a device specifically designed for installation within any listed enclosure and evaluated by a qualified test lab for installation inside any listed enclosure can be safely installed.

In order to provide clarity, we suggest the NEC specifies that a device may only be installed inside an enclosure if it is listed and approved for installation inside any listed enclosure by a qualified test lab. The installation of the device must not force any components (e.g. splices, taps, conductors) out of compliance with the NEC.

To address CMP9's concerns about obstructions in the enclosure, we propose a limit on the amount of space that can be occupied by the device, splices, taps and conductors in any cross-sectional area. Evaluation of this limit should be performed by the Inspector during the standard inspection process. A field evaluation would not be practical as no network of evaluators exists that could handle the required volume.

Public Comment No. 1298-NFPA 70-2015 [Section No. 312.8(B)]

(B) Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

(1) The device or equipment is listed and evaluated and approved for installation within any listed enclosure. [This language would replace the following bullet 1 language completely.]

(1) The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit evaluated for field installation in the specific equipment

(2) The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

I am director of measurement and verification for a company in the Pacific Northwest. We measure performance of homes and businesses in our region and those data feed directly into the regional planning process. We have carried out this work for over 25 years and have installed or overseen installation of rated devices such as power transducers and current transformers in a wide range of electrical panels (manufactured between the mid-1950s and present). All of the equipment we have utilized is rated for use in panels and we have had no long-term, serious issues over hundreds of sites. The intent of the proposed language in this section of the Standard would seem to be to unnecessarily constrain the types of equipment that can be installed in load centers. There is no technical or safety reason I can see for this so I must assume the intent is to artificially limit the supply chain so as to maximize profits for the panel manufacturers. I strenuously object to this limitation as it has no technical or safety basis and would make it much harder for our region to carry out various types of research that are intended to deliver electricity and natural gas resources to consumers at the lowest possible cost.

Public Comment No. 1307-NFPA 70-2015 [ Section No. 312.8(B) ]

(B) Devices and Equipment.
The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

(1) The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit listed and evaluated for field installation in the specific equipment installation within any listed enclosure.

(2) The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

The addition of 312.8 (B) would limit the installation of devices and equipment to only those enclosures that they were specifically assessed within by qualified test labs. Due to the large number of enclosures currently on the market, and the even greater number of discontinued enclosures already in the field, this requirement is so burdensome as to be completely impractical, and would result in the elimination of any 3rd party devices from the market. This includes independent metering devices designed to measure the power use of a variety of end uses. This is critically important for my field - energy efficiency research. Without knowing how much energy something uses in the field, we cannot make accurate calculations of how much energy it saves. Laboratory testing for energy use does not replicate field conditions, which are more varied than the lab can provide. Enclosures are largely similar to one another and it should be fairly straightforward to design a test procedure that can ensure safety in all of them.

(B) Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

1. The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit listed and evaluated for field installation in the specific equipment installation within any listed enclosure.

2. The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

As this provision is currently written, it would be nearly impossible, and therefore impractical, to certify any new accessories for all existing and new models of equipment. It would hinder efforts of homeowners who wish to utilize energy monitoring and management equipment as well as renewable energy and battery backup systems. There are many ways to provide options for fire safety within an electrical system but these regulations should not come at the expense of improving and evolving energy balancing technology and hardware.

Public Comment No. 1367-NFPA 70-2015 [ Section No. 312.8(B) ]

(B) Devices and Equipment.
The wiring space of enclosures for switches or overcurrent devices shall be permitted for to be occupied by devices and equipment where all of the following conditions are met:

1. The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit device evaluated for field installation in the specific equipment switch and overcurrent device enclosures, and

2. The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

As originally worded, it appears this proposal would prohibit the installation of current transformers or meters for energy monitoring in any switch and overcurrent device enclosures unless every possible current transformer or meter was evaluated and listed for use in every possible enclosure. If this interpretation is correct, it puts a financially insurmountable burden on the submetering industry.

The industry as a whole has an excellent safety record with respect to recognized and listed metering devices placed within switch and overcurrent device enclosures. The success of such applications over multiple decades of use, together with the originally proposed wording for [Part B] seems, in practice, to effectively limit devices permitted within switch and overcurrent device enclosures to only those made by the enclosure manufacturer and could thus be perceived within the context of restraint of trade.

Furthermore, this restriction would make it nearly impossible to retrofit submetering into existing homes, commercial, and industrial facilities, especially those using discontinued enclosures for which no current transformers have been approved.

(B) Devices and Equipment.
The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

1. The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit, listed and evaluated for field installation in the specific equipment installation within any listed enclosure.

2. The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

The first draft language would prevent the installation of 3rd party monitors that make use of Current Transformers (CTs) to provide data that supports renewable credits, revenue-grade metering, and conservation efforts that focus on consumer awareness. Further, such data will be important to support the development of micro-grid and battery storage, which are integral technologies to the growth of renewable energy. We believe the proposed change strikes a good balance - both increasing safety and allowing for innovation and interoperability.

Statement of Problem and Substantiation for Public Comment

The proposed modification to section 312.8 puts significant restrictions on the installation of 3rd party devices and equipment to only those enclosures that were assessed by qualified test labs. 3rd part devices play an important role in the growth of home energy management and energy efficiency, connected home devices, renewable energy technologies such as solar and battery storage, and in enabling microgrids and providing utility services such as demand response for a sustainable grid.

Due to the large number of enclosures currently on the market, and the even greater number of discontinued enclosures already in the field, this requirement is so burdensome as to be completely impractical, and would result in the elimination of 3rd party devices that are critical to enabling the above listed technology advancements. We fully recognize CMP9’s concerns around potential obstruction and hazard, and in order to provide clarity, we suggest the NEC specifies that a device may only be installed inside an enclosure if it is listed and approved for installation inside any listed enclosure by a qualified test lab. The installation of the device must not force any components (e.g. splices, taps, conductors) out of compliance with the NEC.

To address CMP9's concerns about obstructions in the enclosure, we propose a limit on the amount of space that can be occupied by the device, splices, taps and conductors in any cross sectional area. Evaluation of this limit should be performed by the Inspector during the standard inspection process. A field evaluation would not be practical as no network of evaluators exists that could handle the required volume.

| Statement: | CMP 9 agrees that the initial revision was excessively broad and carried unintended consequences. The inspection community does have, and has routinely applied, the tools required to police other intrusions into the wiring gutters of this equipment in the event of a problem. This action at this stage, which includes making correlating changes in the parent language, limits the additional specific coverage in this cycle to power monitoring equipment. This is now covered by a comparatively new UL Outline of Investigation (UL 2808, Guide Card XOBA, with markings that describe the CT equipment and the energy monitoring function, such as “energy-monitoring CT”). |
| CMP 9 is retaining the two-part structure of this section so that the new Part B can be easily expanded in the future as may be judged necessary based on subsequent field experience. The final result also includes some of the language from Comment 1178, which was informed by the UL standards activity. |
Public Comment No. 1508-NFPA 70-2015 [Section No. 312.8(B)]

(B) Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

1. The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit evaluated for field installation in the specific equipment.

2. The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

It will be impractical to submit current transformers (CT) for ALL enclosures new or old. Therefore I recommend to use the following statement:

The device or equipment is listed and evaluated for installation within ANY listed enclosure.

Thanks
Sam Seyfi

Statement of Problem and Substantiation for Public Comment

It will be impractical to submit current transformers (CT) for ALL enclosures (new or old). Therefore I recommend to use the following statement:

The device or equipment is listed and evaluated for installation within ANY listed enclosure.

Thanks
Sam Seyfi

Public Comment No. 1510-NFPA 70-2015 [Section No. 312.8(B)]

(B) Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

1. The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit listed and evaluated for field installation in the specific equipment installation within any listed enclosure.

2. The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

The addition of 312.8 (B) would limit the installation of devices and equipment to only those enclosures that they were specifically assessed within by qualified test labs. Due to the large number of enclosures currently on the market, and the even greater number of discontinued enclosures already in the field, this requirement is so burdensome as to be completely impractical, and would result in the elimination of any 3rd party devices from the market. These 3rd party devices have proven to be the only viable way of addressing the current install base of enclosures across the US. 3rd party devices fill a critical role in the growth of renewable energy by providing the necessary sensor data to optimally manage a home’s participation on the grid. Lack of such information will hinder the deployment of technologies such as solar, battery storage, microgrid and demand response which are key to achieving a stable, sustainable grid. In their statement regarding this proposed change, CMP9 references an earlier proposal to allow the installation of utilization equipment which was rejected in the 2011 cycle. We recognize that the wide variety of existing devices classified as ‘utilization equipment’ and not designed for installation inside enclosures could result in obstruction and hazard. However, we propose that a device specifically designed for installation within any listed enclosures and evaluated by qualified test lab for installation inside any listed enclosures can be safely installed. In order to provide clarity, we suggest the NEC specifies that a device may only be installed inside an enclosure if it is listed and approved for installation inside any listed enclosure by a qualified test lab. The installation of the device must not force any components (e.g. splices, taps, conductors) out of compliance with the NEC. To address CMP9’s concerns about obstructions in the enclosure, we propose a limit on the amount of space that can be occupied by the device, splices, taps and conductors in any cross-sectional area. Evaluation of this limit should be performed by the Inspector during the standard inspection process. A field evaluation would not be practical as no network of evaluators exists that could handle the required volume.

Statement of Problem and Substantiation for Public Comment

Sunrun supports the proposed alternative code language for NEC 312.8. The proposed changes offered here eliminate unnecessary restrictions that would keep third party devices from being installed inside enclosures. Implementation of the proposed NEC 312.8 as written would prohibit the placement of home sided sub-metering equipment within enclosures. Effectively this change prohibits the home owner from metering his or her load without the upgrade of the entire panel board, which may render a project economically or technically not feasible. Due to the large number of enclosures currently on the market, and the even greater number of discontinued enclosures already in the field, this requirement would result in the elimination of any third party devices from the market. Residences will not be able to use third party metering for the purposes of assessing their consumption either for general knowledge or analysis of their usage on a time of use rate or other similarly time dependent rate structure. The ability to collect and monitor this data will be important to the growth of renewable energy, providing the necessary sensor data to optimally manage a home's participation on the grid. Lack of such information will hinder the deployment of technologies such as solar, battery storage, micro-grid and demand response which are key to achieving a stable, sustainable grid.

Public Comment No. 1644-NFPA 70-2015 [Section No. 312.8(B)]

(B) Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

1. The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit listed and evaluated for field installation in the specific equipment installation within any listed enclosure.

2. The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

I tend to agree with Neurio Technology Inc's take here, but this even seems like it could quickly escalate into bureaucratic overkill, putting unhelpful burdens on new construction as well as remodels, stifling SAFE, modern, Green Initiatives:

The addition of 312.8 (B) would limit the installation of devices and equipment to only those enclosures that they were specifically assessed within by qualified test labs. Due to the large number of enclosures currently on the market, and the even greater number of discontinued enclosures already in the field, this requirement is so burdensome as to be completely impractical, and would result in the elimination of any 3rd party devices from the market. These 3rd party devices have proven to be the only viable way of addressing the current install base of enclosures across the US.

3rd party devices fill a critical role in the growth of renewable energy by providing the necessary sensor data to optimally manage a home's participation on the grid. Lack of such information will hinder the deployment of technologies such as solar, battery storage, microgrid and demand response which are key to achieving a stable, sustainable grid.

In their statement regarding this proposed change, CMP9 references an earlier proposal to allow the installation of utilization equipment which was rejected in the 2011 cycle. We recognize that the wide variety of existing devices classified as 'utilization equipment' and not designed for installation inside enclosures could result in obstruction and hazard. However, we propose that a device specifically designed for installation within any listed enclosures and evaluated by qualified test lab for installation inside any listed enclosures can be safely installed.

In order to provide clarity, we suggest the NEC specifies that a device may only be installed inside an enclosure if it is listed and approved for installation inside any listed enclosure by a qualified test lab. The installation of the device must not force any components (e.g. splices, taps, conductors) out of compliance with the NEC.

To address CMP9's concerns about obstructions in the enclosure, we propose a limit on the amount of space that can be occupied by the device, splices, taps and conductors in any cross-sectional area. Evaluation of this limit should be performed by the Inspector during the standard inspection process. A field evaluation would not be practical as no network of evaluators exists that could handle the required volume.

National Fire Protection Association Report

http://submittals.nfpa.org/TerraViewWeb/ContentFetcher?commentPara...
Public Comment No. 1648-NFPA 70-2015 [Section No. 312.8(B)]

(B) Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

1. The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed kit evaluated for field installation in the specific equipment listed and evaluated for installation within any listed enclosure.

2. The total area of all conductors, splices, taps, devices, and equipment at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

The addition of 312.8 (B) would limit the installation of devices and equipment to only those enclosures that they were specifically assessed within by qualified test labs. Due to the large number of enclosures currently on the market, and the even greater number of discontinued enclosures already in the field, this requirement is so burdensome as to be completely impractical, and would result in the elimination of any 3rd-party devices from the market. These 3rd-party devices have proven to be the only viable way of addressing the current install base of enclosures across the US.

3rd-party devices fill a critical role in the growth of renewable energy by providing the necessary sensor data to optimally manage a home’s participation on the grid. Lack of such information will hinder the deployment of technologies such as solar, battery storage, micro-grid and demand response which are key to achieving a stable, sustainable grid.

In their statement regarding this proposed change, CMP9 references an earlier proposal to allow the installation of utilization equipment which was rejected in the 2011 cycle. We recognize that the wide variety of existing devices classified as ‘utilization equipment’ and not designed for installation inside enclosures could result in obstruction and hazard. However, we propose that a device specifically designed for installation within any listed enclosures and evaluated by qualified test lab for installation inside any listed enclosures can be safely installed.

In order to provide clarity, we suggest the NEC specifies that a device may only be installed inside an enclosure if it is listed and approved for installation inside any listed enclosure by a qualified test lab. The installation of the device must not force any components (e.g. splices, taps, conductors) out of compliance with the NEC.

To address CMP9’s concerns about obstructions in the enclosure, we propose a limit on the amount of space that can be occupied by the device, splices, taps and conductors in any cross-sectional area. Evaluation of this limit should be performed by the Inspector during the standard inspection process. A field evaluation would not be practical as no network of evaluators exists that could handle the required volume.

CMP 9 is retaining the two-part structure of this section so that the new Part B can be easily expanded in the future as may be judged necessary based on subsequent field experience. The final result also includes some of the language from Comment 1178, which was informed by the UL standards activity.
Public Comment No. 960-NFPA 70-2015 [Section No. 312.8(B)]

(B) Devices and Equipment.

The wiring space of enclosures for switches or overcurrent devices shall be permitted for devices and equipment where all of the following conditions are met:

1. The device or equipment is identified as a field installable accessory as part of the listed equipment, or is a listed product or kit evaluated for field installation in the specific equipment switch and overcurrent device enclosures, and

2. The total area of all conductors, splices, taps, devices, and equipment installed at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.

Statement of Problem and Substantiation for Public Comment

The originally proposed wording would prohibit the installation of UL Listed accessories specifically tested and certified for use in switch and overcurrent device enclosures (e.g. panelboards). As millions of such products are currently installed and there is no evidence of any safety issue resulting from such installation, this seems to be an effort to force manufacturers of such products out of the marketplace. The wording change is both onerous and unfairly restrictive.

CMP 9 is retaining the two-part structure of this section so that the new Part B can be easily expanded in the future as may be judged necessary based on subsequent field experience. The final result also includes some of the language from Comment 1178, which was informed by the UL standards activity.
Paragraph 314.20: Flush-Mounted Installations.
Flush-mounted installations within or behind a surface of concrete, tile, gypsum, plaster, or other noncombustible material, including boxes employing a flush-type cover or faceplate, shall be made so that the front edge of the box, plaster ring, extension ring, or listed extender will not be set back of the finished surface more than 6 mm (1/4 in.).

Flush-mounted installations within or behind a surface of wood or other combustible surface material, boxes, plaster rings, extension rings, or listed extenders shall extend to the finished surface or project therefrom.

Statement of Problem and Substantiation for Public Comment
Have both conditions use the same intro text, the revised wording is now confusing.

Zip: 
Submittal Date: Tue Aug 04 19:56:27 EDT 2015

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-2404-NFPA 70-2015
Statement: CMP 9 agrees that the two paragraphs should use parallel wording. The revision achieves the goal of the submitter, but does so with fewer words. The phrasing “Flush-mounted” need not be duplicated because it occurs verbatim in the section title and therefore applies equally to both paragraphs.
Public Comment No. 1792-NFPA 70-2015 [Section No. 314.23(B)(1)]

(1) Nails and Screws.
Nails and screws, where used as a fastening means, shall secure boxes by using brackets on the outside of the enclosure, or through holes provided by the enclosure manufacturer in the back or a single side of the enclosure, or by using mounting holes in the back or a single side of the enclosure, or they shall pass through the interior within 6 mm (1/4 in.) of the back or ends of the enclosure. Screws shall not be permitted to pass through the box unless exposed threads in the box are protected using approved means to avoid abrasion of conductor insulation. Mounting holes made in the field shall be approved.

Statement of Problem and Substantiation for Public Comment
The Correlating Committee directs the panel to give further consideration to the comments expressed in voting on FR 2410

Submittal Date: Mon Sep 28 15:57:29 EDT 2015

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-2405-NFPA 70-2015
Statement:
The PC submittal correctly restated the relevant comments in the voting, which in turn correctly stated the actual panel action on FR 2410. The action and statement included incorrect text. The correct wording of the statement is as follows:

“This revision corrects the previous text that literally required only the nails and screws to be attached instead of the box, and assures that mounting holes are indeed permitted in the back or sides of a box, correcting previous oversights. The new wording also assures that if such holes are made in the field they are subject to the evaluation of the AHJ as to suitability. This is of particular importance in the case of nonmetallic boxes, where such holes are generally discouraged by manufacturers. Mounting holes drilled in steel boxes are less critical but should still be reviewable and the text in this revision provides for both.”

The Correlating Committee correctly flagged these errors in their Comment 1792, but did not provide the corrected text. This action in concert with Comment 830 provides both the correct Code text as well as a panel statement that properly aligns with and supports the revised text. Note that the legislative text in Comment 830 shows changes from the first draft text (as is required under the rules at this stage), and not from the 2014 NEC. For the benefit of members of the public who will be reviewing the second draft document, the attached word document shows the resulting changes from the 2014 edition.
(1) Nails and Screws.
Nails and screws, where used as a fastening means, shall secure boxes by using brackets on the outside of the enclosure, or through holes provided by the enclosure manufacturer in the back or a single side of the enclosure, or by using mounting holes in the back or a single side of the enclosure, or they shall pass through the interior within 6 mm (1/4 in.) of the back or ends of the enclosure. Screws shall not be permitted to pass through the box unless exposed threads in the box are protected using approved means to avoid abrasion of conductor insulation. Mounting holes made in the field shall be approved permitted.

Statement of Problem and Substantiation for Public Comment
IEC’s position is to replace the word “approved” with “permitted” in the last sentence of 314.23(B)(1) - (FR 2410)
It is unreasonable to require an AHJ to approve a mounting hole made in the field.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-2405-NFPA 70-2015
Statement: The PC submittal correctly restated the relevant comments in the voting, which in turn correctly stated the actual panel action on FR 2410. The action and statement included incorrect text. The correct wording of the statement is as follows:

“This revision corrects the previous text that literally required only the nails and screws to be attached instead of the box, and assures that mounting holes are indeed permitted in the back or sides of a box, correcting previous oversights. The new wording also assures that if such holes are made in the field they are subject to the evaluation of the AHJ as to suitability. This is of particular importance in the case of nonmetallic boxes, where such holes are generally discouraged by manufacturers. Mounting holes drilled in steel boxes are less critical but should still be reviewable and the text in this revision provides for both.”

The Correlating Committee correctly flagged these errors in their Comment 1792, but did not provide the corrected text. This action in concert with Comment 830 provides both the correct Code text as well as a panel statement that properly aligns with and supports the revised text. Note that the legislative text in Comment 830 shows changes from the first draft text (as is required under the rules at this stage), and not from the 2014 NEC. For the benefit of members of the public who will be reviewing the second draft document, the attached word document shows the resulting changes from the 2014 edition.
314.27 Outlet Boxes.

(A) Boxes at Luminaire or Lampholder Outlets.

Outlet boxes or fittings and outlet boxes containing locking support and mounting receptacle used in combination with compatible attachment fitting, designed for the support of luminaires and lampholders, and installed as required by 314.23, shall be permitted to support a luminaire or lampholder.

(1) Vertical Surface Outlets.

Boxes used at luminaire or lampholder outlets in or on a vertical surface shall be identified and marked on the interior of the box to indicate the maximum weight of the luminaire that is permitted to be supported by the box if other than 23 kg (50 lb).

Exception: A vertically mounted luminaire or lampholder weighing not more than 3 kg (6 lb) shall be permitted to be supported on other boxes or plaster rings that are secured to other boxes, provided that the luminaire or its supporting yoke, or the lampholder, is secured to the box with no fewer than two No. 6 or larger screws.

(2) Ceiling Outlets.

At every outlet used exclusively for lighting, the box shall be designed or installed so that a luminaire or lampholder may be attached. Boxes shall be required to support a luminaire weighing a minimum of 23 kg (50 lb). A luminaire that weighs more than 23 kg (50 lb) shall be supported independently of the outlet box, unless the outlet box is listed for not less than the weight to be supported. The interior of the box shall be marked by the manufacturer to indicate the maximum weight the box shall be permitted to support.

(B) Floor Boxes.

Boxes listed specifically for this application shall be used for receptacles located in the floor.

Exception: Where the authority having jurisdiction judges them free from likely exposure to physical damage, moisture, and dirt, boxes located in elevated floors of show windows and similar locations shall be permitted to be other than those listed for floor applications. Receptacles and covers shall be listed as an assembly for this type of location.

(C) Boxes at Ceiling-Suspended (Paddle) Fan Outlets.

Outlet boxes or outlet box systems used as the sole support of a ceiling-suspended (paddle) fan shall be listed, shall be marked by their manufacturer as suitable for this purpose, and shall not support ceiling-suspended (paddle) fans that weigh more than 32 kg (70 lb). For outlet boxes or outlet box systems designed to support ceiling-suspended (paddle) fans that weigh more than 16 kg (35 lb), the required marking shall include the maximum weight to be supported.

Outlet boxes containing listed locking support and mounting receptacle used in combination with compatible recognized attachment fitting designed for the support of ceiling-suspended (paddle) fans, and installed as required by 314.23, shall be permitted to support ceiling-suspended (paddle) fans.

Where spare, separately switched, ungrounded conductors are provided to a ceiling-mounted outlet box, in a location acceptable for a ceiling-suspended (paddle) fan in one-family, two-family, or multifamily dwellings, the outlet box or outlet box system shall be listed for sole support of a ceiling-suspended (paddle) fan.

(D) Utilization Equipment.

Boxes used for the support of utilization equipment other than ceiling-suspended (paddle) fans shall meet the requirements of 314.27(A) for the support of a luminaire that is the same size and weight.

Exception: Utilization equipment weighing not more than 3 kg (6 lb) shall be permitted to be supported on other boxes or plaster rings that are secured to other boxes, provided the equipment or its supporting yoke is secured to the box with no fewer than two No. 6 or larger screws.

(E) Separable Attachment Fittings.

Outlet boxes shall be permitted to support listed locking support and mounting receptacles used in combination with compatible attachment fittings designed for the support of equipment covered within and subject to all weight and orientation limits contemplated by the listing. Where such fittings are used, the equipment mounted shall comply with 314.27(A) through (D) as applicable. Where the supporting receptacle is installed within a box, it shall be included in the fill calculation covered in 314.16(B)(4).

Statement of Problem and Substantiation for Public Comment

This Public Comment seeks to do exactly as directed by the Correlating Committee by correcting transcription errors from the First Draft meeting. This was highlighted by the Correlating Committee (CC) in the First Draft, Correlating Committee Note No. 97-2015. The CC wrote:

"The Correlating Committee informs the public that transcription errors have occurred in the processing of the First Revision. It is imperative to open and read the first revision that applies to this section and to read all of the voting comments."
Public Inputs 4443 and 4665 suggested changed text in 314.27(A) and the second paragraph of 314.27(C); these changes were inadvertently added and should be removed. The accuracy of this Public Comment is verified when viewing the Panel Statement in FR 2411. The newly added 314.27(E) was approved by the Panel and should remain as shown in the Public Comment.

The Panel voted two other editorial changes that are reflected as the Panel intended in the Public Comment and are noted in the ballot comments. These changes are:

314.27(A)(2) changed

“A luminaire that weighs more than 23 kg (50 lb) shall be supported independently of the outlet box, unless the outlet box is listed and marked on the interior of the box to indicate the maximum weight the box shall be permitted to support.”

to

“A luminaire that weighs more than 23 kg (50 lb) shall be supported independently of the outlet box, unless the outlet box is listed for not less than the weight to be supported. The interior of the box shall be marked by the manufacturer to indicate the maximum weight the box shall be permitted to support.”

Also, 314.27(C) in the 3rd paragraph, the Panel changed “single-family” to “one family” and “multi-family” to “multifamily” and should remain in the section, as shown in the Public Comment.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-2406-NFPA 70-2015 This revision fully correlates the new text in the first revision that created 314.27(E) with revisions being made to the definition of a receptacle in Article 100 as well as coverage in 422.18 and 422.33. The general reference to 314.27 also allows for broader applications of this design approach than just luminaires and ceiling-suspended (paddle) fans. In addition, the action on this Comment addresses the transcription errors that crept into the both the purported panel action (the Code text) on FR 2411, and the panel statement. CMP 9 calls attention to the following information contained in comments in the voting, to which the Correlating Committee comment (#1793) refers: “For the benefit of members of the public reading these actions, the third paragraph of the panel statement must begin “In (A)(2), this revision ...” for obvious reasons. In addition, there was additional text voted by CMP 9 to support the revision (see PI #348) to the second paragraph of (C). In this report, it should have been formatted as a concluding sentence, worded as follows: “With respect to the change from “single-family” to “one-family” in the second paragraph of (C), CMP 9 is matching the literal text with the defined terms in Article 100.” This paragraph completes the public record and allows users to fully understand the relevant substantiation.

Public Comment No. 831-NFPA 70-2015 [Section No. 314.27]

314.27 Outlet Boxes.

(A) Boxes at Luminaire or Lampholder Outlets.
Outlet boxes or fittings and outlet boxes containing locking support and mounting receptacle used in combination with compatible attachment fitting, designed for the support of luminaires and lampholders, and installed as required by 314.23, shall be permitted to support a luminaire or lampholder.

(1) Vertical Surface Outlets.
Boxes used at luminaire or lampholder outlets in or on a vertical surface shall be identified and marked on the interior of the box to indicate the maximum weight of the luminaire that is permitted to be supported by the box if other than 23 kg (50 lb).

Exception: A vertically mounted luminaire or lampholder weighing not more than 3 kg (6 lb) shall be permitted to be supported on other boxes or plaster rings that are secured to other boxes, provided that the luminaire or its supporting yoke, or the lampholder, is secured to the box with no fewer than two No. 6 or larger screws.

(2) Ceiling Outlets.
At every outlet used exclusively for lighting, the box shall be designed or installed so that a luminaire or lampholder may be attached. Boxes shall be required to support a luminaire weighing a minimum of 23 kg (50 lb). A luminaire that weighs more than 23 kg (50 lb) shall be supported independently of the outlet box, unless the outlet box is listed for not less than the weight to be supported. The interior of the box shall be marked by the manufacturer to indicate the maximum weight the box shall be permitted to support.

(B) Floor Boxes.
Boxes listed specifically for this application shall be used for receptacles located in the floor.

Exception: Where the authority having jurisdiction judges them free from likely exposure to physical damage, moisture, and dirt, boxes located in elevated floors of show windows and similar locations shall be permitted to be other than those listed for floor applications. Receptacles and covers shall be listed as an assembly for this type of location.

(C) Boxes at Ceiling-Suspended (Paddle) Fan Outlets.
Outlet boxes or outlet box systems used as the sole support of a ceiling-suspended (paddle) fan shall be listed, shall be marked by their manufacturer as suitable for this purpose, and shall not support ceiling-suspended (paddle) fans that weigh more than 32 kg (70 lb). For outlet boxes or outlet box systems designed to support ceiling-suspended (paddle) fans that weigh more than 16 kg (35 lb), the required marking shall include the maximum weight to be supported.

Outlet boxes containing listed locking support and mounting receptacle used in combination with compatible recognized attachment fitting designed for the support of ceiling-suspended (paddle) fans, and installed as required by 314.23, shall be permitted to support ceiling-suspended (paddle) fans.

Where spare, separately switched, ungrounded conductors are provided to a ceiling-mounted outlet box, in a location acceptable for a ceiling-suspended (paddle) fan in one-family, two-family, or multifamily dwellings, the outlet box or outlet box system shall be listed for sole support of a ceiling-suspended (paddle) fan.

(D) Utilization Equipment.
Boxes used for the support of utilization equipment other than ceiling-suspended (paddle) fans shall meet the requirements of 314.27(A) for the support of a luminaire that is the same size and weight.

Exception: Utilization equipment weighing not more than 3 kg (6 lb) shall be permitted to be supported on other boxes or plaster rings that are secured to other boxes, provided the equipment or its supporting yoke is secured to the box with no fewer than two No. 6 or larger screws.

(E) Separable Attachment Fitting Termination Devices for Support of Luminaires and Ceiling-Suspended Fans.
Outlet boxes required in 314.27(A) and (C) shall be permitted to support listed locking support and mounting receptacles mounting termination devices used in combination with compatible attachment fittings designed, compatible fittings and identified, for the support of equipment covered within and subject to all weight and orientation limits contemplated by of luminaires or of ceiling-suspended fans within the weight and mounting-orientation limits of the listing. Where such fittings are used, the equipment mounted shall comply with 314.27(A) through (D) as applicable. Where the supporting receptacle the supporting termination device is installed within a box, it shall be included in the fill calculation covered in 314.16(B)(4).

Statement of Problem and Substantiation for Public Comment
The FR text in 314.27(A) and (C) relating to locking support and mounting receptacles is not necessary since 314.27(E) covers the requirements.
The term “receptacles” is changed to “termination devices” since these devices do not conform to the NEC definition of a receptacle

Public Comment No. 1794-NFPA 70-2015 [ Section No. 314.28(A)(3) ]

(3) Smaller Dimensions.

Listed boxes or listed conduit bodies of dimensions less than those required in 314.28(A)(1) and (A)(2) shall be permitted for installations of combinations of conductors that are less than the maximum conduit or tubing fill (of conduits or tubing being used) permitted by Table 1 of Chapter 9.

Listed conduit bodies of dimensions less than those required in 314.28(A)(2), and having a radius of the curve to the centerline not less than that indicated in Table 2 of Chapter 9 for one-shot and full-shoe benders, shall be permitted for installations of combinations of conductors permitted by Table 1 of Chapter 9. These conduit bodies shall be marked to show they have been specifically evaluated in accordance with this provision.

Where the permitted combinations of conductors for which the box or conduit body has been listed are less than the maximum conduit or tubing fill permitted by Table 1 of Chapter 9, the box or conduit body shall be permanently marked with the maximum number and maximum size of conductors permitted. For other conductor sizes and combinations, the total cross-sectional area of the fill shall not exceed the cross-sectional area of the conductors specified in the marking, based on the type of conductor identified as part of the product listing.

Informational Note: Unless otherwise specified, the applicable product standards evaluate the fill markings covered here based on conductors with Type XHHW insulation.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs that the panel reconsider the text of the informational note in regard to possible mandatory language, assuring compliance with the NEC Style Manual.

Submittal Date: Mon Sep 28 15:59:47 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: CMP 9 does not agree that the original language constituted mandatory material. The requirement is in the product standard; this information will be of great assistance in the field in terms of providing a basis for correctly applying the requirement. The original task group report during the input stage on this subject would have made the insulation reference to XHHW mandatory by placing it in 314.28(A)(3) as code text. That recommendation was converted by CMP 9 to an informational note so the reference would not be binding on the developer of the product standard. The need for explanatory information for users in the field was raised with some panel members by NFPA staff members who had problems presenting these calculations during NEC seminars. Current product marking protocols do not provide this information, and this is resulting in extensive confusion and uneven field enforcement. CMP 9 continues to strongly support the user-friendly initiative it has taken for the 2017 cycle accordingly.
Public Comment No. 1123-NFPA 70-2015 [Section No. 314.28(E)(1)]

(1) Installation.
Power distribution blocks installed in boxes shall be listed and labeled. Power distribution blocks installed on the line side of the service equipment shall be listed identified for the purpose and marked accordingly.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-2407-NFPA 70-2015
Statement:

The Panel has provided clear instructions for the marking required rather than “for the purpose”.

CMP 9 declines to make the requested changes to add “and labeled” in this section because it would contradict an instruction from the Correlating Committee that this change is not to proceed in this cycle (First Correlating Revision No. 143). In its instruction, the Correlating Committee noted that it has appointed a task group to consider this throughout the NEC. CMP 9 awaits a final decision of the Correlating Committee in this matter.

The standard of product acceptance in this code provision is “listed”. Qualified testing laboratories all enforce comparable operational limitations on the use of their labels. Listing must be evidenced by a label, either on the equipment or on the smallest unit shipping carton if the characteristics of the product preclude a label. If a label comes off, it must be reapplied by test lab personnel; it cannot be sent through the mail or otherwise. At some point in every IAEI section meeting for the past few decades, this topic is covered in exquisite detail. CMP 9 is therefore unconvinced of the technical merits of the arguments supporting the change, but will comply with any instruction provided by the Correlating Committee.
Public Comment No. 1235-NFPA 70-2015 [New Section after 314.70(B)]

(4) Conduit bodies that are used to change direction are not permitted for use with shield cables rated 5kV or higher. They may be pulled through a body that does not change direction.

Additional Proposed Changes

Statement of Problem and Substantiation for Public Comment

This is my second effort to disallow shielded cables in conduit bodies due to numerous troubles in the field. Shielded cable manufacturers recommend against the use of conduit bodies since the minimum bending radius is not sufficient in these bodies and results in an unsafe and unreliable installation. Often the result is that the entire must be changed to eliminate conduit bodies which requires complete replacement of the cable which adds financial burden to the end user or installer.

Submittal Date: Thu Sep 24 14:53:06 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: CMP 9 reaffirms its original statement on the PI (#3802) that this comment supports. The applicable rules are already in the NEC, at 300.34. The substantiation for this comment failed to address any of the arguments made by CMP 9. In addition, the proposed language would interfere with the initiative taken by CMP 9 under FR #2414 that allows future design and evaluation for medium voltage systems of conduit bodies with two 45-degree entries that do not impose a more severe bend radius than that allowed for the entering raceways.
Pull and junction boxes and handhole enclosures shall provide approved space and dimensions for the installation of conductors, and they shall comply with the specific requirements of this section. Conduit bodies shall be permitted if they meet the dimensional requirements for boxes.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs that further consideration be given to the comments expressed in voting on FR 2415. This action will be considered as a public comment.

Committee Statement
Committee Action: Rejected
Resolution: The text in the first draft, which deleted the exception to 314.71, is correct. In this instance errors occurred in the report of the Panel statement on the first revision, as described in the ballot comments. The correct Panel statement was: "This exception is not appropriate for medium voltage applications. The correlating committee should send this public input to CMP 11 for information, where it should be reviewed for possible action in Part XI of Article 430."
Public Comment No. 1168-NFPA 70-2015 [Section No. 320.10]

### Statement of Problem and Substantiation for Public Comment

This added language is confusing as to the application of AC cable in health care facilities. The text is unnecessary and will cause needless confusion for installers and AHJs.

- **Resolution:** SR-1801-NFPA 70-2015
- **Statement:** CMP-7 deletes item (2) as it is unnecessary as 320.10 is not an all inclusive list.
### Public Comment No. 559-NFPA 70-2015 [Section No. 320.10]

#### 320.10 Uses Permitted.

Type AC cable shall be permitted as follows:

1. For feeders and branch circuits in both exposed and concealed installations
2. For life safety and critical branch circuits of the essential electrical systems in health care facilities where permitted by 517.31(C)(3)(1) and 517.31(C)(3)(3)
3. In cable trays
4. In dry locations
5. Embedded in plaster finish on brick or other masonry, except in damp or wet locations
6. To be run or fished in the air voids of masonry block or tile walls where such walls are not exposed or subject to excessive moisture or dampness

**Informational Note:** The “Uses Permitted” is not an all-inclusive list.

### Statement of Problem and Substantiation for Public Comment

IEEE statement opposing the First Revision:FR1807 The inclusion of For life safety and critical branch circuits of the essential electrical systems in health care facilities where permitted by 517.31(C)(3)(1) and 517.31(C)(3)(3) in the uses permitted section is not typical. There was already an “Information Note: The “Uses Permitted” is not an all-inclusive list.” and this inclusion does not provide additional technical use in application for the installation just more specific as to location(s). Article 517 is specific to Health Care Facilities and should list the type of cable for the system specified per CMP15 jurisdiction.

### Committee Statement

**Committee Action:** Rejected but see related SR  
**Resolution:** SR-1801-NFPA 70-2015  
**Statement:** CMP-7 deletes item (2) as it is unnecessary as 320.10 is not an all inclusive list.
320.10 Uses Permitted.
Type AC cable shall be permitted as follows:

1. For feeders and branch circuits in both exposed and concealed installations
2. For life safety and critical branch circuits of the essential electrical systems in health care facilities where permitted by 517.31(C)(3)(1) and 517.31(C)(3)(3)
3. In cable trays
4. In dry locations
5. Embedded in plaster finish on brick or other masonry, except in damp or wet locations
6. To be run or fished in the air voids of masonry block or tile walls where such walls are not exposed or subject to excessive moisture or dampness

Informational Note: The "Uses Permitted” is not an all-inclusive list.

Statement of Problem and Substantiation for Public Comment

Adding this specific permission to use MC and AC for these Article 517 applications strongly implies that other cable and raceway wiring methods that do not include this specific permission in their respective xxx.10 sections are not acceptable for these Article 517 applications. For example 358.10 for EMT does not have this specific permission.

Informational Note: The “Uses Permitted” is not an all-inclusive list.

Statement of Problem and Substantiation for Public Comment
The Panel statement shows that Panel 7 requested Panel 15 review. Panel 15 has subsequently resolved all PI's allowing the use of AC Cable in 517.30(C)(3)(1). Therefore, this PI should be resolved, since there is no permitted use for AC cable in those locations. Leaving this text could lead to confusion and misinterpretation of NEC requirements.

Statement: CMP-7 deletes item (2) as it is unnecessary as 320.10 is not an all inclusive list.
Public Comment No. 260-NFPA 70-2015 [Section No. 320.30(A)]

(A) General.
Type AC cable shall be supported and secured by staples, listed cable ties identified as Type 2S or Type 21S listed and identified for securement and support, straps, hangers, or similar fittings or other approved means designed and installed so as not to damage the cable.

Statement of Problem and Substantiation for Public Comment

The language of all cable tie-related FR's between CMP 7 and CMP 8 should be harmonized. The difference between the CMP 7 FR's (1809, 1815, 1821 and 1830) and the CMP 8 FR's (2166, 2170, 2104 and 2115) is that those from CMP 7 maintained the cable tie Type classifications. CMP 8 removed these Types with the following committee statement:

"Listing of cable ties approved for support of flexible conduits and cables is appropriate as the standard requires markings that identify critical performance ranges that can impact their suitability for use, including minimum and maximum operating temperature and resistance to ultraviolet light for outdoor installations. The proposed new requirements will provide objective determination for suitability of cable ties for this use".

Article 324  Flat Conductor Cable: Type FCC

Part I. General

324.1 Scope.
This article covers a field-installed wiring system for branch circuits incorporating Type FCC cable and associated accessories as defined by the article. The wiring system is designed for installation under carpet squares.

324.2 Definitions.

Bottom Shield.
A protective layer that is installed between the floor and Type FCC flat conductor cable to protect the cable from physical damage and may or may not be incorporated as an integral part of the cable.

Cable Connector.
A connector designed to join Type FCC cables without using a junction box.

FCC System.
A complete wiring system for branch circuits that is designed for installation under carpet squares.

Informational Note: The FCC system includes Type FCC cable and associated shielding, connectors, terminators, adapters, boxes, and receptacles.

Insulating End.
An insulator designed to electrically insulate the end of a Type FCC cable.

Metal Shield Connections.
Means of connection designed to electrically and mechanically connect a metal shield to another metal shield, to a receptacle housing or self-contained device, or to a transition assembly.

Top Shield.
A grounded metal shield covering under-carpet components of the FCC system for the purposes of providing protection against physical damage.

Transition Assembly.
An assembly to facilitate connection of the FCC system to other wiring systems, incorporating (1) a means of electrical interconnection and (2) a suitable box or covering for providing electrical safety and protection against physical damage.

Type FCC Cable.
Three or more flat copper conductors placed edge-to-edge and separated and enclosed within an insulating assembly.

324.6 Listing Requirements.
Type FCC cable and associated fittings shall be listed.

Part II. Installation

324.10 Uses Permitted.

(A) Branch Circuits.
Use of FCC systems shall be permitted both for general-purpose and appliance branch circuits and for individual branch circuits.

(B) Branch-Circuit Ratings.

(1) Voltage.
Voltage between ungrounded conductors shall not exceed 300 volts. Voltage between ungrounded conductors and the grounded conductor shall not exceed 150 volts.

(2) Current.
General-purpose and appliance branch circuits shall have ratings not exceeding 20 amperes. Individual branch circuits shall have ratings not exceeding 30 amperes.

(C) Floors.
Use of FCC systems shall be permitted on hard, sound, smooth, continuous floor surfaces made of concrete, ceramic, or composition flooring, wood, and similar materials.

(D) Walls.
Use of FCC systems shall be permitted on wall surfaces in surface metal raceways.
(E) Damp Locations.
Use of FCC systems in damp locations shall be permitted.

(F) Heated Floors.
Materials used for floors heated in excess of 30°C (86°F) shall be identified as suitable for use at these temperatures.

(G) System Height.
Any portion of an FCC system with a height above floor level exceeding 2.3 mm (0.090 in.) shall be tapered or feathered at the edges to floor level.

324.12 Uses Not Permitted.
FCC systems shall not be used in the following locations:

1) Outdoors or in wet locations
2) Where subject to corrosive vapors
3) In any hazardous (classified) location
4) In residential, school, and hospital buildings

324.18 Crossings.
Crossings of more than two Type FCC cable runs shall not be permitted at any one point. Crossings of a Type FCC cable over or under a flat communications or signal cable shall be permitted. In each case, a grounded layer of metal shielding shall separate the two cables, and crossings of more than two flat cables shall not be permitted at any one point.

324.30 Securing and Supporting.
All FCC system components shall be firmly anchored to the floor or wall using an adhesive or mechanical anchoring system identified for this use. Floors shall be prepared to ensure adherence of the FCC system to the floor until the carpet squares are placed.

324.40 Boxes and Fittings.
(A) Cable Connections and Insulating Ends.
All Type FCC cable connections shall use connectors identified for their use, installed such that electrical continuity, insulation, and sealing against dampness and liquid spillage are provided. All bare cable ends shall be insulated and sealed against dampness and liquid spillage using listed insulating ends.

(B) Polarization of Connections.
All receptacles and connections shall be constructed and installed so as to maintain proper polarization of the system.

(C) Shields.
1) Top Shield.
A metal top shield shall be installed over all floor-mounted Type FCC cable, connectors, and insulating ends. The top shield shall completely cover all cable runs, corners, connectors, and ends.

2) Bottom Shield.
A bottom shield shall be installed beneath all Type FCC cable, connectors, and insulating ends.

(D) Connection to Other Systems.
Power feed, grounding connection, and shield system connection between the FCC system and other wiring systems shall be accomplished in a transition assembly identified for this use.

(E) Metal-Shield Connectors.
Metal shields shall be connected to each other and to boxes, receptacle housings, self-contained devices, and transition assemblies using metal-shield connectors.

324.41 Floor Coverings.
Floor-mounted Type FCC cable, cable connectors, and insulating ends shall be covered with carpet squares not larger than 1.0 m (39.37 in.) square. Carpet squares that are adhered to the floor shall be attached with release-type adhesives.

324.42 Devices.
(A) Receptacles.
All receptacles, receptacle housings, and self-contained devices used with the FCC system shall be identified for this use and shall be connected to the Type FCC cable and metal shields. Connection from any grounding conductor of the Type FCC cable shall be made to the shield system at each receptacle.

(B) Receptacles and Housings.
Receptacle housings and self-contained devices designed either for floor mounting or for in-wall or on-wall mounting shall be permitted for use with the FCC system. Receptacle housings and self-contained devices shall incorporate means for facilitating entry and termination of Type FCC cable and for electrically connecting the housing or device with the metal shield. Receptacles and self-contained devices shall comply with 406.4. Power and communications outlets installed together in common housing shall be permitted in accordance with 800.133(A)(1) (d), Exception No. 2.
324.56 Splices and Taps.

(A) FCC Systems Alterations.

Alterations to FCC systems shall be permitted. New cable connectors shall be used at new connection points to make alterations. It shall be permitted to leave unused cable runs and associated cable connectors in place and energized. All cable ends shall be covered with insulating ends.

(B) Transition Assemblies.

All transition assemblies shall be identified for their use. Each assembly shall incorporate means for facilitating entry of the Type FCC cable into the assembly, for connecting the Type FCC cable to grounded conductors, and for electrically connecting the assembly to the metal cable shields and to equipment grounding conductors.

324.60 Grounding.

All metal shields, boxes, receptacle housings, and self-contained devices shall be electrically continuous to the equipment grounding conductor of the supplying branch circuit. All such electrical connections shall be made with connectors identified for this use. The electrical resistivity of such shield system shall not be more than that of one conductor of the Type FCC cable used in the installation.

Part III. Construction Specifications

324.100 Construction.

(A) Type FCC Cable.

Type FCC cable shall be listed for use with the FCC system and shall consist of three, four, or five flat copper conductors, one of which shall be an equipment grounding conductor.

(B) Shields.

(1) Materials and Dimensions.

All top and bottom shields shall be of designs and materials identified for their use. Top shields shall be metal. Both metallic and nonmetallic materials shall be permitted for bottom shields.

(2) Resistivity.

Metal shields shall have cross-sectional areas that provide for electrical resistivity of not more than that of one conductor of the Type FCC cable used in the installation.

324.101 Corrosion Resistance.

Metal components of the system shall be either corrosion resistant, coated with corrosion-resistant materials, or insulated from contact with corrosive substances.

324.112 Insulation.

The insulating material of the cable shall be moisture resistant and flame retardant. All insulating materials in the FCC systems shall be identified for their use.

324.120 Markings.

(A) Cable Marking.

Type FCC cable shall be clearly and durably marked on both sides at intervals of not more than 610 mm (24 in.) with the information required by 310.120(A) and with the following additional information:

(1) Material of conductors
(2) Maximum temperature rating
(3) Ampacity

(B) Conductor Identification.

Conductors shall be clearly and durably identified on both sides throughout their length as specified in 310.110.

<td></td>
</tr>
</tbody>
</table>

Statement of Problem and Substantiation for Public Comment

Commercial and retail building owners are rapidly adopting alternate flooring covering for use in their facilities in addition to or instead of carpet squares, such as modular vinyl planks and tile, laminate and hard wood. For example luxury vinyl use in commercial buildings rose 32.5% in 2014 alone. These alternate floor coverings offer the building owner a highly attractive and low maintenance flooring. However they still need/demand the ability to provide power and data to open areas which do not have traditional cabling pathways and need/want the flexibility of using both FCC (Flat Conductor Cable - power) in the same manner that they are presently allowed with carpet squares. Often the installation of FCC cable is the only acceptable solution to providing powering to the middle of the room. UL
Fact Finding Report finds that FCC cable can safely be installed under these alternate floors. Modular tiles and planks are as easily removed as carpet squares allowing for access and maintenance of FCC cable.

Submitter Information Verification

Submitter Full Name: Tony Beam
Organization: CommScope
Street Address:
City:
State:
Zip:
Submittal Date: Fri Sep 25 14:42:15 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The submitter did not indicate what changes were being requested in the Public Comment as required by NFPA Regulations Governing The Development of NFPA Standards 4.4.4.3(c). From the materials submitted, it does not appear that the modular tile and plank flooring is as easy to remove as carpet squares. Video links submitted show the use of knives and screwdrivers being used to remove the tile, either of which could damage Type FCC cable installed underneath. Carpet squares installed over Type FCC are required to have release-type adhesives, allowing the carpet squares to be removed with minimal use of tools.
324.6 Listing Requirements.
Type FCC cable and associated fittings shall be listed and labeled.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

Public Comment No. 494-NFPA 70-2015 [New Section after 324.12]

Public Comment on Panel 7 results for PI#3753

As co-authors of Public Input #3753 our intent was to allow under floor wiring systems in schools and hospital non-patient care areas to address the need for power in open offices, classrooms and training rooms. The products that meet Article 324 provide a system of power distribution without a tripping issue that other floor solutions create.

Given the Panel 7 concerns of safety in schools and hospital buildings we began working on installing Beta Sites in schools to demonstrate that Article 324 products do provide a safe environment. During the process we discovered that the school solution would be best served using low voltage (Class I and II). After further investigation and research we found that there are a number of low voltage (Class I and II) products that can be used to provide a safe environment in schools and hospital non-patient care areas.

Based on our discovery we would submit the following language to enhance the Electrical Code under Article 324.12(4).

Add:

Exception 1: Class I and II wiring systems, listed for the use, are allowed in school class rooms, offices, laboratories, lounges and libraries when installed in compliance with Article 725.

Exception 2: Class I and II wiring systems, listed for the use, are allowed in hospital conference rooms, training rooms, lounges, nurse’s stations and offices when installed in compliance with Article 725.

Statement of Problem and Substantiation for Public Comment

Problem: Accessing power source at the point of use in schools and hospital non-patient environments with open class rooms, conference rooms, libraries, laboratories, teacher lounges and offices. Current solutions for existing spaces are cumbersome and expensive to install, and if they are not routed through trenches will create a tripping hazard. Technology is evolving rapidly and the need to incorporate low voltage into our space planning is growing exponentially.

Our proposal would provide the ability to access the power source for powering lap tops, cell phone charging, tablet use and recharging, LED lighting and energy saving controls in open rooms at the point of use with the ability to make changes to the space as technology changes. Class I and Class II wiring systems, listed for the use and installed under the requirements of Article 725 would provide additional safety to the end user. Flat Conductor Cable, Article 324, provides flexibility of installation, safety of installation and eliminates tripping hazards to the occupants.

Currently 57% of our schools (K-12 and Colleges) and 62% our hospitals were constructed prior to the influx of technology that is now needed to perform our daily work and to meet our needs for teaching and learning. Flat Conductor Cable, Article 324, allow existing infrastructures to be upgraded quicker and less expensively to meet today's and tomorrow's technology tools.

Committee Statement

Committee Action: Rejected
Resolution: Type FCC cable is listed at 300 volts according to the UL Guide Card, Category code IKKT. The exceptions requested by the submitter are not appropriate for Article 324 since the wiring systems described are not Type FCC cable. It is likely the submitter is referring to CMUC communications cable listed to UL 444.
324.12 Uses Not Permitted.

FCC systems shall not be used in the following locations:

1. Outdoors or in wet locations
2. Where subject to corrosive vapors
3. In any hazardous (classified) location
4. In residential, school, and hospital buildings

Statement of Problem and Substantiation for Public Comment

FCC systems have been proven to be safe and reliable when installed and maintained in accordance with the NEC 70 electrical code. School classrooms, computer laboratories, administration offices, teacher lounges, student lounges, reception workstations, social meeting areas, media centers and libraries do not present safety risks that are not already provided for within the current electrical code. Likewise, non-patient care and non-patient rooms in hospital and emergency care centers, such as administrative offices, training rooms, media centers, reception workstations and social meeting areas do not present safety risks that are not already provided for within the current electrical code.

Submittal Date: Fri Sep 25 15:53:45 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-1804-NFPA 70-2015
Statement: The revised language will allow Type FCC cable in administrative office areas of hospitals and schools.
324.112 Insulation.

The insulating material of the cable shall be moisture resistant and flame retardant. All insulating materials in the FCC systems shall be identified for their use.

Informational Note: The requirements associated with the term flame retardant for each type of cable or insulation are contained within the product standard for the relevant cable or insulation. (See also 310.104).

Statement of Problem and Substantiation for Public Comment

The panel stated that the testing requirements are not needed for this article. The informational note proposed is being revised to explain that information on the term "flame retardant" is contained in the product standard. This is important because the term "flame retardant" as such is not an appropriate term without clarification because the term flame retardant simply refers to the additives that are used to improve fire performance, unless the fire performance is clarified.

Submittal Date: Tue Sep 22 15:42:29 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: Type FCC cable is required to be listed. The informational note provides no useful information to code users.
328.30 Support.
Type MV cable terminated in equipment, installed in pull boxes, or in vaults shall be secured and supported by metallic or nonmetallic supports suitable to withstand the weight, by listed cable ties listed and identified for securement and support, or other approved means, at intervals not exceeding 1.5 m (5 ft) from terminations or a maximum of 1.8 m (6 ft) between supports.

Statement of Problem and Substantiation for Public Comment

The language of all cable tie-related FR's between CMP 7 and CMP 8 should be harmonized. The difference between the CMP 7 FR's (1809, 1815, 1821 and 1830) and the CMP 8 FR's (2166, 2170, 2104 and 2115) is that those from CMP 7 maintained the cable tie Type classifications. CMP 8 removed these Types with the following committee statement:

"Listing of cable ties approved for support of flexible conduits and cables is appropriate as the standard requires markings that identify critical performance ranges that can impact their suitability for use, including minimum and maximum operating temperature and resistance to ultraviolet light for outdoor installations. The proposed new requirements will provide objective determination for suitability of cable ties for this use".

Public Comment No. 1167-NFPA 70-2015 [Section No. 330.10(A)]

(A) General Uses.
Type MC cable shall be permitted as follows:

1. For services, feeders, and branch circuits.
2. For power, lighting, control, and signal circuits.
3. Indoors or outdoors.
4. Exposed or concealed.
5. To be direct buried where identified for such use.
6. In cable tray where identified for such use.
7. In any raceway.
8. As aerial cable on a messenger.
9. In hazardous (classified) locations where specifically permitted by other articles in this Code.
10. For life safety and critical branch circuits of the essential electrical systems in health care facilities where permitted by "517.31(C)(3)(1) and 517.31(C)(3)(3)".
11. In dry locations and embedded in plaster finish on brick or other masonry except in damp or wet locations.
12. In wet locations where a corrosion-resistant jacket is provided over the metallic covering and any of the following conditions are met:
   14. The metallic covering is impervious to moisture.
   15. A jacket resistant to moisture is provided under the metal covering.
   16. The insulated conductors under the metallic covering are listed for use in wet locations.
13. Where single-conductor cables are used, all phase conductors and, where used, the grounded conductor shall be grouped together to minimize induced voltage on the sheath.

Statement of Problem and Substantiation for Public Comment

This new text is confusing as to the application of MC cable in health care facilities and will create installation questions for installers and enforcers. The text is unnecessary.

Resolution: SR-1806-NFPA 70-2015
Statement: CMP-7 deletes item (10) as it is unnecessary as 330.10 is not an all inclusive list.
(A) General Uses.
Type MC cable shall be permitted as follows:

1. For services, feeders, and branch circuits.
2. For power, lighting, control, and signal circuits.
3. Indoors or outdoors.
4. Exposed or concealed.
5. To be direct buried where identified for such use.
6. In cable tray where identified for such use.
7. In any raceway.
8. As aerial cable on a messenger.
9. In hazardous (classified) locations where specifically permitted by other articles in this Code.
10. For life safety and critical branch circuits of the essential electrical systems in health care facilities where permitted by 517.31(C)(3)(1) and 517.31(C)(3)(3).
11. In dry locations and embedded in plaster finish on brick or other masonry except in damp or wet locations.
12. In wet locations where a corrosion-resistant jacket is provided over the metallic covering and any of the following conditions are met:
   14. The metallic covering is impervious to moisture.
   15. A jacket resistant to moisture is provided under the metal covering.
   16. The insulated conductors under the metallic covering are listed for use in wet locations.
13. Where single-conductor cables are used, all phase conductors and, where used, the grounded conductor shall be grouped together to minimize induced voltage on the sheath.

Statement of Problem and Substantiation for Public Comment

IEEE statement opposing the First Revision:FR1818 The inclusion of For life safety and critical branch circuits of the essential electrical systems in health care facilities where permitted by 517.30(C)(3)(1) and 517.30(C)(3)(3) in the uses permitted section is not typical. There is an “Information Note: The “Uses Permitted” is not an all-inclusive list.” and this inclusion does not provide additional technical use in application for the installation just more specific as to location(s). Article 517 is specific to Health Care Facilities and should list the type of cable for the system specified per CMP15 jurisdiction.

   14. A jacket resistant to moisture is provided under the metal covering.
   15. The insulated conductors under the metallic covering are listed for use in wet locations.
16. Where single-conductor cables are used, all phase conductors and, where used, the grounded conductor shall be grouped together to minimize induced voltage on the sheath.

Statement of Problem and Substantiation for Public Comment

The Panel statement shows that Panel 7 requested Panel 15 review. Panel 15 has subsequently resolved all PI's allowing the use of MC Cable in 517.30(C)(3)(1). Therefore, this PI should be resolved, since there is no permitted use for MC cable in those locations. Leaving this text could lead to confusion and misinterpretation of NEC requirements.

Statement of Problem and Substantiation for Public Comment

The "follow the building finish" language would be impractical in a commercial and industrial installation. Where it is common practice to install the MC cables exposed in between junior beams with bridle ring supports, or installed with trapezoid strut hanger from a ceiling. What is a building finish? and is it always present?

The article has uses where it is not following the building surface such as 330.30(D)(3) & (6) & (7).

This is too restrictive a section for MC under all applications and some relief should be provided. If taken literally the cable needs to touch the building surface for its entire length, the way caddy hanger and beam clamps are installed on a beam the cable is usually two to three inches away from a beam, the new section addresses from beam to beam but not the run a long the beam installation, this usually is in a type I and II constructed building. I would suggest removing the whole section.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

Statement: CMP 7 removes Type 2S and Types 21S and adds "listed, labeled and identified for securement and support" to provide information to the AHJ regarding the suitability of equipment they encounter.
334.108 Equipment Grounding Conductor.

In addition to the insulated conductors, the cable shall have an insulated, covered, or bare equipment grounding conductor only.

Statement of Problem and Substantiation for Public Comment

I agree with the Committee Statement stating “the need for Qualified Persons performing all electrical installations.” Education is very important and a must for everyone. But in reality education can help but can not solve problems with equipment design flaws.

In order for a problem to be solved thru education thousands of people must be involved. The electrical industry must first recognize the problem and the teachers must be made aware of it. Producing documentation and addressing the problem in classrooms across the nation on a consistent basis is just not reality. The logistics of thousands of people required to communicate the problem is just too large and will take many years for the problem to be corrected. Over time the problem can be addressed thru the many classrooms and in the field but accidents can and will happen.

The problem of accidental contact in residential receptacles of the neutral (grounded conductor) and the bare grounding conductor in non-metallic sheathed cable and causing Objectionable Current which in turn can cause shocks, fires or electrocution can easily be solved. Not 100% but very close. Inspection can not solve the problem as they do not have the time to look behind every wall plate. Using the Standard three prong tester used for testing receptacles can not solve the problem. If the neutral (grounded conductor) screw touches the bare grounding conductor the tester will show “Correct Wiring”. And to wait years for something to be taught and still not prevent the accidental touching does not help the situation.

Insulating the bare grounding conductor in non-metallic sheathed cable will prevent the accidental touching of the neutral (grounded conductor) and the bare grounding conductor and will prevent Objectionable Current and it's associated risks of shocks, fires and electrocution. Why? Because all of the conductors are insulated. Can you prevent someone from purposely connecting neutrals (grounded conductor) and grounding conductors together? No. Education can help but not solve the problem.

What comes to mind is a quote that I quoted in the “Statement of Problem and Substantiation for Public Input”. I’m changing that quote to be more reflective of the electrical industry.

“You don’t design an electrical installation or electrical equipment on the assumption that everyone will do the right thing. You design it assuming people will make mistakes and build it in ways that withstand and minimize error”

In closing my recommendation to the Committee is to change the electrical code to allow only an insulated grounding conductor in non-metallic sheathed cable. It will not solve all problems, but it will solve the problem of accidental contact between neutral (grounded conductor) and bare grounding conductors in residential receptacles. This small change will make all residential wiring safer, which is essentially what we all want. Any time the risks of shocks, fires or electrocution can be minimized, that change should be made now. Not at some point in the future. Just like with tamper proof receptacles making it safer for young children inserting metal objects into the receptacle and possibly getting shocked. Educating the public should be enough to implement the purchase of devices to prevent these hazards, but it takes too much time. Requiring all residential receptacles to be tamper proof now eliminates the time to educate and puts safety in the hands of people immediately. Education is a must and absolutely required, but as I described above no education is required to absolutely prevent unintentional mistakes. Insulating the grounding conductor will prevent the problem of Objectionable Current causing shocks, fires or electrocution now, not sometime in the future. Why wait? Solve the problem now; insulate the grounding conductor in Non-metallic Sheathed Cable!

334.112 Insulation.

The insulated power conductors shall be one of the types listed in Table 310.104(A) that are suitable for branch-circuit wiring or one that is identified for use in these cables. Conductor insulation shall be rated at 90°C (194°F).

Informational Note 1: Types NM, NMC, and NMS cable identified by the markings NM-B, NMC-B, and NMS-B meet this requirement.

Informational Note 2: The requirements associated with the term flame retardant for each type of cable or insulation are contained within the product standard for the relevant cable or insulation. (See also 310.104).

Statement of Problem and Substantiation for Public Comment

The panel stated that the testing requirements are not needed for this article. The informational note proposed is being revised to explain that information on the term "flame retardant" is contained in the product standard. This is important because the term "flame retardant" as such is not an appropriate term without clarification because the term flame retardant simply refers to the additives that are used to improve fire performance, unless the fire performance is clarified.

Committee Statement

Committee Action: Rejected
Resolution: An informational note about flame retardant is not needed since this is covered in the product listing.
Uses Permitted.

Type TC cable shall be permitted to be used as follows:

(1) For power, lighting, control, and signal circuits.
(2) In cable trays, including those with mechanically discontinuous segments up to 300 mm (1 ft).
(3) In raceways.
(4) In outdoor locations supported by a messenger wire.
(5) For Class 1 circuits as permitted in Parts II and III of Article 725.
(6) For non–power-limited fire alarm circuits if conductors comply with the requirements of 760.49.

(7) Between a cable tray and the utilization equipment or device(s), provided all of the following apply:
   (8) The cable is Type TC-ER.
   (9) The cable is installed in industrial establishments where the conditions of maintenance and supervision ensure that only qualified persons service the installation.
   (10) The cable is continuously supported and protected against physical damage using mechanical protection such as struts, angles, or channels.
   (11) The cable that complies with the crush and impact requirements of Type MC cable and is identified with the marking “TC-ER”.
   (12) The cable is secured at intervals not exceeding 1.8 m (6 ft).
   (13) Equipment grounding for the utilization equipment is provided by an equipment grounding conductor within the cable. In cables containing conductors sized 6 AWG or smaller, the equipment grounding conductor must be provided within the cable or, at the time of installation, one or more insulated conductors must be permanently identified as an equipment grounding conductor in accordance with 250.119(B).

Exception to (7): Where not subject to physical damage, Type TC-ER shall be permitted to transition between cable trays and between cable trays and utilization equipment or devices for a distance not to exceed 1.8 m (6 ft) without continuous support. The cable shall be mechanically supported where exiting the cable tray to ensure that the minimum bending radius is not exceeded.

(14) Where installed in wet locations, Type TC cable shall also be resistant to moisture and corrosive agents.

(15) In one- and two-family dwelling units, Type TC-ER cable containing both power and control conductors that is identified for pulling through structural members shall be permitted to be installed between a power inlet box or permanently installed generator and the transfer equipment. Type TC-ER cable used as exterior wiring shall be installed per the requirements of Part II of Article 340. Type TC-ER cable used as interior wiring shall be installed per the requirements of Part II of Article 334. Exception to (15): Where the generator and transfer equipment have terminals rated 75°C (167°F) or higher, the allowable ampacity of the conductor shall be determined in accordance with 110.14(C)(1)(a)(3) and 310.15. The 90°C (194°F) rating shall be permitted to be used for adjustment and correction calculations, provided the final derated ampacity does not exceed that of a 75°C (167°F) conductor.

Informational Note: TC-ER cable that is suitable for pulling through structural members is marked “JP.”

(16) Direct buried, where identified for such use

Informational Note: See 310.15(A)(3) for temperature limitation of conductors.

Statement of Problem and Substantiation for Public Comment

Articles 334.80 and 340.80 could be interpreted to limit the ampacity of the conductors to 60°C. This temperature limitation is due to devices such as receptacles and light switches having terminals rated only for a 60°C temperature rating. The terminal lugs in the generator and transfer equipment manufactured by Generac Power Systems are rated at 75°C at the generator breaker terminals and 75°C at the neutral and equipment ground bar/lugs and 90°C on the transfer mechanism lugs. If the insulation temperature rating of the conductors and temperature rating of the lugs have a 75°C minimum temperature rating, why limit the ampacity to the 60°C rating when 110.14(C)(1)(a)(3) permits the higher temperature rating if the equipment is listed and labeled for use with such conductors.

First Revision No. 1832-NFPA 70-2015 [Section No. 336.10]
Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-1808-NFPA 70-2015
Statement: The revised language will allow generator and associated equipment with terminals rated 75C or greater to be used with TC cable without being limited to 60C.

The revised language will permit TC-ER cable to be used for supplying equipment other than generators in one- and two-family dwelling units.

CMP-7 has reviewed the record per the Correlating Committee’s request and consideration was given to the ballot comments expressed in FR 1840.

The use of the word "identified" is appropriate. The informational note and the marking requirement will trigger a change to the product standard requiring a joist pull test for cable that will be allowed to be marked "JP". Type TC cable is required to be listed.

Type TC cable has a nonmetallic jacket and construction similar to wiring methods commonly found in residential applications, like Types NM, UF and SE. It is unclear why the other types would be allowed for this application and Type TC would not be.

CMP-7 also adds Informational Note 2 to alert users of the separation requirements of Class 2 and 3 conductors from electric light, power or Class 1 circuits.
Uses Permitted.

Type TC cable shall be permitted to be used as follows:

(1) For power, lighting, control, and signal circuits.
(2) In cable trays, including those with mechanically discontinuous segments up to 300 mm (1 ft).
(3) In raceways.
(4) In outdoor locations supported by a messenger wire.
(5) For Class 1 circuits as permitted in Parts II and III of Article 725.
(6) For non–power-limited fire alarm circuits if conductors comply with the requirements of 760.49.
(7) Between a cable tray and the utilization equipment or device(s), provided all of the following apply:
   (8) The cable is Type TC-ER.
   (9) The cable is installed in industrial establishments where the conditions of maintenance and supervision ensure that only qualified persons service the installation.
   (10) The cable is continuously supported and protected against physical damage using mechanical protection such as struts, angles, or channels.
   (11) The cable that complies with the crush and impact requirements of Type MC cable and is identified with the marking "TC-ER".
   (12) The cable is secured at intervals not exceeding 1.8 m (6 ft).
   (13) Equipment grounding for the utilization equipment is provided by an equipment grounding conductor within the cable. In cables containing conductors sized 6 AWG or smaller, the equipment grounding conductor must be provided within the cable or, at the time of installation, one or more insulated conductors must be permanently identified as an equipment grounding conductor in accordance with 250.119(B).

Exception to (7): Where not subject to physical damage, Type TC-ER shall be permitted to transition between cable trays and between cable trays and utilization equipment or devices for a distance not to exceed 1.8 m (6 ft) without continuous support. The cable shall be mechanically supported where exiting the cable tray to ensure that the minimum bending radius is not exceeded.

(14) Where installed in wet locations, Type TC cable shall also be resistant to moisture and corrosive agents.

(15) In one- and two-family dwelling units, Type TC-ER cable containing both power and control conductors that is identified for pulling through structural members shall be permitted to be installed between a power inlet box or permanently installed generator and the transfer equipment supply equipment without being in a cable tray or raceway. Type TC-ER cable used as exterior wiring shall be installed per the requirements of Part II of Article 340. Type TC-ER cable used as interior wiring shall be installed per the requirements of Part II of Article 334.

Informational Note: TC-ER cable that is suitable for pulling through structural members is marked "JP."

(16) Direct buried, where identified for such use

Informational Note: See 310.15(A)(3) for temperature limitation of conductors.

Statement of Problem and Substantiation for Public Comment

Revise new list item (9) to 336.10 to permit TC-ER cable to be used for supplying equipment other than generators as proposed in PI 4359. NM and UF cable is presently permitted for this so TC-ER cable should be also. The concern for misusing TC-ER cables also applies to NM cable.

Informational Note: TC-ER cable that is suitable for pulling through structural members is marked “JP.”

(12) Direct buried, where identified for such use

Informational Note: See 310.15(A)(3) for temperature limitation of conductors.

Statement of Problem and Substantiation for Public Comment

Due to the incorrect formatting used in the online systems I have posted my recommended change below as well as the substantiation below the code language as directed by NFPA.

336.10 Uses Permitted.

Type TC cable shall be permitted to be used as follows:

For power, lighting, control, and signal circuits.

In cable trays, including those with mechanically discontinuous segments up to 300 mm (1 ft).

In raceways.

In outdoor locations supported by a messenger wire.
For Class 1 circuits as permitted in Parts II and III of Article 725.

For non-power-limited fire alarm circuits if conductors comply with the requirements of 760.49.

Between a cable tray and the utilization equipment or device(s), provided all of the following apply:
- The cable is Type TC-ER.
- The cable is installed where conditions of maintenance and supervision ensure that only qualified persons service the installation.
- The cable is continuously supported and protected against physical damage using mechanical protection such as struts, angles, or channels.
- The cable that complies with the crush and impact requirements of Type MC cable and is identified with the marking “TC–ER”.
- The cable is secured at intervals not exceeding 1.8 m (6 ft).

Equipment grounding for the utilization equipment is provided by an equipment grounding conductor within the cable. In cables containing conductors sized 6 AWG or smaller, the equipment grounding conductor must be provided within the cable or, at the time of installation, one or more insulated conductors must be permanently identified as an equipment grounding conductor in accordance with 250.119(B).

Exception to (7): Where not subject to physical damage, Type TC-ER shall be permitted to transition between cable trays and between cable trays and utilization equipment or devices for a distance not to exceed 1.8 m (6 ft) without continuous support. The cable shall be mechanically supported where exiting the cable tray to ensure that the minimum bending radius is not exceeded.

Where installed in wet locations, Type TC cable shall also be resistant to moisture and corrosive agents.

In one- and two-family dwelling units, Type TC-ER cable containing both power and control conductors that is identified for pulling through structural members shall be permitted to be installed between a power inlet box or permanently installed generator and the transfer equipment. Type TC-ER cable used as exterior wiring shall be installed per the requirements of Part II of Article 340. Type TC-ER cable used as interior wiring shall be installed per the requirements of Part II of Article 334.

Informational Note: TC-ER cable that is suitable for pulling through structural members is marked “JP.”

Direct buried, where identified for such use

Informational Note: See 310.15(A)(3) for temperature limitation of conductors.

Substantiation: The reference to "industrial use only" in the permitted use item should be removed. The there is no technical substantiation as to why you would limit Type TC-ER cable from a Cable Tray to Equipment only within an Industrial Setting. In fact, many commercial settings have the same need and they also are maintained by maintenance individuals who are skilled and trained. In fact, in the 2020 NEC I will be presenting an entire revamping of Article 336 to remove this stigmatized misunderstanding on Type TC Cable. Type TC-ER Cable is robust and will hold up much better than Type SE Cable, yet the NEC permits Type SE-R cable to run all over a structures. The construction of Type TC-ER is again more robust than type SE Cable, can meet or exceed all the required properties of Type SE Cable and should be permitted to be used in the same environments at the least. I am the Manager of Codes and Standards for Encore Wire and when I presented this concept to the other members of the NEMA Wire and Cable group at a meeting in Florida, not a single individual could point to why it would not be acceptable other than the fact some companies don't product Type TC Cable. This cable is a very strong and reliable cable and it should be permitted in many others uses that what is stated here. The construction is of the same inner conductors (THHN/THWN-2 or XHHW-2) and the outer sheathing is thicker and stronger than Type SE Cable yet it is limited to its permitted use without any known substantiation as to why.

Related Item
First Revision No. 1832-NFPA 70-2015 [Section No. 336.10]
336.10 Uses Permitted.

Type TC cable shall be permitted to be used as follows:

(1) For power, lighting, control, and signal circuits.
(2) In cable trays, including those with mechanically discontinuous segments up to 300 mm (1 ft).
(3) In raceways.
(4) In outdoor locations supported by a messenger wire.
(5) For Class 1 circuits as permitted in Parts II and III of Article 725.

The cable shall be mechanically supported where exiting the cable tray to ensure that the minimum bending radius is not exceeded.

(14) Where installed in wet locations, Type TC cable shall also be resistant to moisture and corrosive agents.

(15) In one- and two-family dwelling units, Type TC-ER cable containing both power and control conductors that is listed for pulling through structural members shall be installed per the requirements of Part II of Article 340. Type TC-ER cable used as interior wiring shall be installed per the requirements of Part II of Article 334. Informational Note: TC-ER cable that is suitable for pulling through structural members is marked “JP.”

(16) Direct buried, where identified for such use

Informational Note: See 310.15(A)(3) for temperature limitation of conductors.

Statement of Problem and Substantiation for Public Comment

This cable is currently being installed as interior wiring for both air conditioning equipment as well as (specific manufactures) optional standby (generator) installation. If CMP-7 is in agreement that this product is suitable for unlimited interior cable installations (exposed and concealed) where not installed in a raceway or associated with a tray system, then it should not limit its’ use to only generator installations. If my suggestion to expand its use and require a listed product (change the UL listing card) is to excessive then I suggest it needs further investigation and a return to the 2014 language. I am sure the code panel will make the right decision.

The cable shall be mechanically supported where exiting the cable tray to ensure that the minimum bending radius is not exceeded.

(14) Where installed in wet locations, Type TC cable shall also be resistant to moisture and corrosive agents.
(15) In one- and two-family dwelling units, Type TC-ER cable containing both power and control conductors that is identified for pulling through structural members shall be permitted to be installed between a power inlet box or permanently installed generator and the transfer equipment. Type TC-ER cable used as exterior wiring shall be installed per the requirements of Part II of Article 340. Type TC-ER cable used as interior wiring shall be installed per the requirements of Part II of Article 334.

  Informational Note: TC-ER cable that is suitable for pulling through structural members is marked “JP.”

(16)
(17) Direct buried, where identified for such use

  Informational Note: See 310.15(A)(3) for temperature limitation of conductors.

Statement of Problem and Substantiation for Public Comment

No change to Item 7.
FR 1840 should be reversed. Type TC Cable is limited to installations in cable trays, raceways and outdoor locations supported by a messenger wire, and according to 336.10(7), is only permitted to be exposed in industrial establishments where the conditions of maintenance and supervision ensure that only qualified persons service the installation. Type TC Cable, which is primarily designed for use in cable tray, should not take exception to installation in conduit (or cable tray) for residential installations even with additional joist pull testing.

First Revision No. 1840-NFPA 70-2015 [Detail]

Submitter Information Verification
Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-1808-NFPA 70-2015
Statement:
The revised language will allow generator and associated equipment with terminals rated 75C or greater to be used with TC cable without being limited to 60C.

The revised language will permit TC-ER cable to be used for supplying equipment other than generators in one- and two-family dwelling units.

CMP-7 has reviewed the record per the Correlating Committee’s request and consideration was given to the ballot comments expressed in FR 1840.

The use of the word "identified" is appropriate. The informational note and the marking requirement will trigger a change to the product standard requiring a joist pull test for cable that will be allowed to be marked "JP". Type TC cable is required to be listed.

Type TC cable has a nonmetallic jacket and construction similar to wiring methods commonly found in residential applications, like Types NM, UF and SE. It is unclear why the other types would be allowed for this application and Type TC would not be.

CMP-7 also adds Informational Note 2 to alert users of the separation requirements of Class 2 and 3 conductors from electric light, power or Class 1 circuits.
336.116 Jacket. The outer jacket shall be a flame-retardant, nonmetallic material. 

Informational Note: The requirements associated with the term flame retardant for each type of cable or insulation are contained within the product standard for the relevant cable or insulation. (See also 310.104).

Statement of Problem and Substantiation for Public Comment

The panel stated that the testing requirements are not needed for this article. The informational note proposed is being revised to explain that information on the term “flame retardant” is contained in the product standard. This is important because the term “flame retardant” as such is not an appropriate term without clarification because the term flame retardant simply refers to the additives that are used to improve fire performance, unless the fire performance is clarified.

Submittal Date: Tue Sep 22 15:50:38 EDT 2015

Committee Statement

Committee Action: Rejected  
Resolution: An informational note about flame retardant is not needed since this is covered in the product listing.
(4) Installation Methods for Branch Circuits and Feeders.

(a) **Interior Installations.** In addition to the provisions of this article, Type SE service-entrance cable used for interior wiring shall comply with the installation requirements of Part II of Article 334, excluding 334.80. Type SE cable with ungrounded conductor sizes 10 AWG and smaller, where Type SE cable is installed in thermal insulation, the ampacity shall be in accordance with 60°C (140°F) conductor temperature rating. The maximum conductor temperature rating shall be permitted to be used for ampacity adjustment and correction purposes, if the final derated ampacity does not exceed that for a 60°C (140°F) rated conductor.

   **Informational Note No. 1:** See 310.15(A)(3) for temperature limitation of conductors.

   **Informational Note No. 2:** For the installation of main power feeder conductors in dwelling units refer to 310.15(B)(7).

(b) **Exterior Installations.** In addition to the provisions of this article, service-entrance cable used for feeders or branch circuits, where installed as exterior wiring, shall be installed in accordance with Part I of Article 225. The cable shall be supported in accordance with 334.30. Type USE cable installed as underground feeder and branch circuit cable shall comply with Part II of Article 340.

   **Exception:** Single-conductor Type USE and multi-rated USE conductors shall not be subject to the ampacity limitations of Part II of Article 340.

**Statement of Problem and Substantiation for Public Comment**

I would ask the panel to reconsider their acceptance of this new language. As stated my one panel member there (as of this date) remains no technical documentation to support that Type SE Cable installed as an interior wiring method is not susceptible to thermal damage within its loading range when installed within thermal insulation. This was argued to exhaustion during the 2011 renewal cycle. As a user of the code and a student of the related science of our industry it is beyond my comprehension that a conductor sized larger than No. 10 AWG will not experience an increased $I^2R$ loss than the smaller cables. Also the comment that smaller Type NM Cables in the parent PI 1828 and reference to 334.80 is a stretch. 334.80 governs all Type NM cables which may contain conductor sizes up to No. 2 AWG (155 A Cu 90A AL). The compromise to exclude the reference to 334.80 during the 2011 cycle with the requirement to limit its ampacity to the 60 degree column when installed in insulation was somewhat given the lack of interest in independent testing.

</tr>
</tbody>
</table>
(4) Installation Methods for Branch Circuits and Feeders.

(a) Interior Installations. In addition to the provisions of this article, Type SE service-entrance cable used for interior wiring shall comply with the installation requirements of Part II of Article 334, excluding 334.80. For Type SE cable with ungrounded conductor sizes 10 AWG and smaller where installed in thermal insulation, the ampacity shall be in accordance with 60°C (140°F) conductor temperature rating. The maximum conductor temperature rating shall be permitted to be used for ampacity adjustment and correction purposes, if the final derated ampacity does not exceed that for a 60°C (140°F) rated conductor.

Informational Note No. 1: See 310.15(A)(3) for temperature limitation of conductors.

Informational Note No. 2: For the installation of main power feeder conductors in dwelling units refer to 310.15(B)(7).

(b) Exterior Installations. In addition to the provisions of this article, service-entrance cable used for feeders or branch circuits, where installed as exterior wiring, shall be installed in accordance with Part I of Article 225. The cable shall be supported in accordance with 334.30. Type USE cable installed as underground feeder and branch circuit cable shall comply with Part II of Article 340.

Exception: Single-conductor Type USE and multi-rated USE conductors shall not be subject to the ampacity limitations of Part II of Article 340.

Statement of Problem and Substantiation for Public Comment

The submitter has not provided a Fact Finding or other substantiation that #10 and larger conductors should be exempted from the requirements of this Section. There is no substantiation provided that larger SE cables behave differently than other types. There has been at least one published failure of SE cable in thermal insulation that failed and almost caused a fire. It is unlikely that there would be reporting of failures since no reporting is required.

Exception: Single-conductor Type USE and multi-rated USE conductors shall not be subject to the ampacity limitations of Part II of Article 340.

Statement of Problem and Substantiation for Public Comment

No change to informational notes.

FR 1828 should be reversed. No technical substantiation was provided to exempt larger sized Type SE cable from the ampacity requirements of 334.80 where the cable is installed in thermal insulation. Exemption of the ampacity requirement based on the size of the conductors is not technically substantiated. The Panel has requested technical support for several code cycles showing that Type SE cable behaves differently from NM or UF cable when installed in thermal insulation, but no such information has been provided. Revision based on size does not address the concern for overheating where larger sized cables are installed in thermal insulation.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant, the manufacturer has the option of removing the mark from the product with the mark, or holding the shipment and bringing the product into compliance. In either case the “listing” is impacted, as the “listing” is created at the time of the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacturer remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL's have similar requirements.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacturer remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

National Fire Protection Association Report
Committee Statement

Committee Action: Rejected

Resolution: The Correlating Committee has appointed a Task Group to address the “Listed and Labeled” Public Inputs for the 2020 NEC. This issue needs correlation throughout the Code so that there is consistency. The use of a Task Group to achieve this is necessary. It is acceptable to wait for the 2020 NEC to properly address and correlate this issue since a safety hazard has not been identified in the substantiations of either the Public Input or Comment pertaining to conduit, tubings and fittings. CMP-8 cannot accept “and labeled” until the definition of “Labeled” is addressed by the Task Group.
Add Exception

Exception: When PVC conduits are directly buried or are encased in an underground ductbank, Type MV-105 rated cables shall be permitted to be installed in PVC ducts rated 90C.

Statement of Problem and Substantiation for Public Comment

MV-105 rated cables and utility medium voltage (non-UI) cables rated 105C are often installed in underground ducts and operated with a 105C conductor temperature. The outer jacket of cables operating with a 105C conductor temperature is at 90C. Thus the section of the cable that is contact with the duct is only at 90C which is within the ducts rating. 1000 volt rated cables that operate are rated 90C have an insulation temperature of 90C since the insulation is much thinner and results in little if any temperature drop across the insulation wall.

The UL standard cited by the panel does not take the temperature differential drop across the insulation of medium voltage cables. The acceptance of this proposal would motivate conduit manufacturers to pursue a 105C rating.

A similar proposal will be made to change Section 353.10(6).

Since the NEC voted to accept 105C rated cables in the 1990's, the NEC should permit them to be installed in an NM duct without an ampacity penalty and the associated confusion.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

**Submittal Date:** Thu Aug 27 16:03:32 EDT 2015

### Committee Statement

**Committee Action:** Accepted  
**Resolution:** SR-2102-NFPA 70-2015  
**Statement:** This revision to the first draft text second revision clarifies that EMT shall be permitted for both exposed and concealed work in dry, damp and wet locations.
358.12  Uses Not Permitted.

EMT shall not be used under the following conditions:

(1) Where subject to severe physical damage

(2) For the support of luminaires or other equipment except conduit bodies no larger than the largest trade size of the tubing

Exception: Aluminum fittings and enclosures shall be permitted to be used with steel EMT where not subject to severe corrosive influences.

Statement of Problem and Substantiation for Public Comment

All references to dissimilar metals have been moved to section 358.14 therefore this exception does not belong under 358.12 and should be deleted. The exception does not have to be moved to 358.14 as the intent of the exception has been included in the wording for the new section 358.14 Dissimilar Metals.

Committee Statement

Committee Action: Accepted
Resolution: SR-2103-NFPA 70-2015
Statement: As a first revision to Article 358, all references to dissimilar metals were moved to section 358.14, Dissimilar Metals. The content of the exception to 358.12 was included in the wording of 358.14 as part of that revision. Therefore, the exception to 358.12 is no longer necessary and can be deleted.
Public Comment No. 781-NFPA 70-2015 [Section No. 358.30(A)]

(A) Securely Fastened.

EMT shall be securely fastened in place at least every 3 m (10 ft). In addition, each EMT run between termination points shall be securely fastened within 900 mm (3 ft) of each outlet box, junction box, device box, cabinet, conduit body, or other tubing termination.

Exception No. 1: Fastening of unbroken lengths shall be permitted to be increased to a distance of 1.5 m (5 ft) where structural members do not readily permit fastening within 900 mm (3 ft) of the outlet box, junction box, device box, cabinet, conduit body, or other tubing termination.

Exception No. 2: For concealed work in finished buildings or prefinished wall panels where such securing is impracticable, unbroken lengths (without coupling) of EMT shall be permitted to be fished.

Statement of Problem and Substantiation for Public Comment

To avoid confusion and misinterpretations, and improve readability of the Code.

“Securely fastened in place AT LEAST EVERY 3 m (10 ft)” is the same as saying “securely fastened in place NO LESS THAN EVERY 3 m (10 ft)”. Effectively, EMT in an installation could be secured every 30 m (100 ft) and the installation would be in compliance with this misworded requirement. In reality, “at least” should be “at most”.

Elsewhere in Chapter 3, CMP-8 has chosen to use the unequivocal words “at intervals not to exceed” where similar minimum securement requirements appear.

Statement of Problem and Substantiation for Public Comment

The committee responded to PI-1408 with the following explanation:

"The installation requirements of the proposed article are already adequately addressed in Article 368, Parts I-IV. Busways are available in a wide range of constructions and are suitable for use in many applications including in service entrance, feeder, and branch circuits. While busways are generally designed and built in accordance with various standards, including UL857 and IEEE C37.23, it is not CMP-8’s intention to include dimensional information found in product standards, such as conductor sizes, in this installation code. No substantiation was presented to allow bus systems in areas where subject to physical damage. While CMP-8 recognizes that some busway systems are designed and marked for support spans of 12 feet or even more, there is no substantiation provided to increase the default support span from 5 feet to 12 feet. The present requirements in Article 368 are clear and adequate. The submitter has not provided evidence that a safety issue exists that would warrant the additional code language."

This isn’t necessarily a safety issue as much as it is a proposal to address a product that doesn't match the text presently in Art. 368. Busways are normally considered in the petrochemical industry to be the small to medium sized modular systems that can be installed in manufacturing facilities where there are plug on disconnects and taps to equipment. And, according to 368.17(A) overcurrent protection would need to be provided to protect the busway. The new article I've proposed would allow transformer secondary side bus duct to be installed without overcurrent protection per Art. 368, but in accordance with Section 240.21. Also, Art. 368 for example doesn't provide information such as the proposed definitions for segregated and non-seg bus ducts. I’d like to request the Panel reconsider and create new Art. 369. Or, at least accept parts of the proposed text that would make Art. 368 applicable to large metal enclosed bus ducts.

I'm not passionate about the 12ft. spacing on the bus duct. Section 368.30 allows bus duct designed for spans more than 5ft. to be installed.

I would like to respectfully request the Chair appoint a small task group to take a hard look at this issue before voting on the resolution.

Committee Statement

Committee Action: Rejected
Resolution: CMP8 reaffirms the action and statement associated with NFPA 70 Public Input No.1408. The present definition in 368.2 does not exclude the "Metal-enclosed bus duct" constructions that the submitter wishes to add. While the construction types that the submitter wishes to define appear in the IEEE C37.23 product standard, they do not appear in this Code nor do they appear in the proposed "Metal-enclosed bus duct" Article and as such inclusion of the definitions is not appropriate per the NEC Style Manual section 2.2.2.1. The panel recognizes that busways are presently used in transformer secondary conductor applications. Exception No. 1 of 368.17(C) explains that overcurrent protection in such feeder applications may be as outlined in 240.21. The language in 368.1 is general and not intended to define the uses permitted and uses not permitted for busway, which can be found in 368.10 and 368.12, respectively.
Public Comment No. 316-NFPA 70-2015 [ New Section after 368.320 ]

### Statement of Problem and Substantiation for Public Comment

Contrary to the panel statement provided during the Public Input stage, major manufacturer's of metal enclosed bus duct do not consider their product to be busways. This comment offers new information that I believe needs to be included in the NEC. Among the new material, it includes definitions not currently found in the NEC and also allows the bus duct to be used in the manner that it is today such as for transformer secondary conductors. Section 368.1 doesn't allow busways to be utilized for transformer secondaries. I respectfully ask the committee to reconsider their decision based on this revised comment. This material wouldn't change anything that isn't being done today. It would simply plug a hole in the NEC.

### Committee Statement

**Committee Action:** Rejected

**Resolution:** CMP8 is unable to identify any new information provided with this public comment. CMP8 reaffirms the action and statement associated with NFPA 70 Public Input No.1408. The panel recognizes that busways are presently used in transformer secondary conductor applications. Exception No. 1 of 368.17(C) explains that overcurrent protection in such feeder applications may be as outlined in 240.21. The language in 368.1 is general and not intended to define the uses permitted and uses not permitted for busway, which can be found in 368.10 and 368.12, respectively.
370.80 Ampacity of Conductors.

(A) The ampacity of conductors in cablebus shall be in accordance with Table 310.15(B)(17) and Table 310.15(B)(19) for installations up to and including 2000 volts, or with Table 310.60(C)(69) and Table 310.60(C)(70) for installations 2001 to 35,000 volts.

(B) Ampacity of Cables, Rated 2000 Volts or Less, in Cablebus that terminate at equipment with conductor temperature limitations.

(1) Single-Conductor Cables. The allowable ampacity of single-conductor cables shall be as permitted by 310.15(A)(2). The adjustment factors of 310.15(B)(3)(a) shall not apply to the ampacity of cables in cablebus. The ampacity of single conductor cables nominally rated 2000 volts or less, shall comply with the following:

(a) Where installed according to the requirements of 370.30, the ampacities for 600 kcmil and larger single conductor cables in ventilated cablebus shall not exceed 75 percent of the allowable ampacities in Table 310.15(B)(17) and Table 310.15(B)(19). Where cablebus are continuously covered for more than 1.8 m (6 ft) with solid unventilated covers, the ampacities for 600 kcmil and larger cables shall not exceed 70 percent of the allowable ampacities in Table 310.15(B)(17) and Table 310.15(B)(19).

(b) Where installed according to the requirements of 370.30, the ampacities for 1/0 AWG through 500 kcmil single-conductor cables in ventilated cablebus shall not exceed 65 percent of the allowable ampacities in Table 310.15(B)(17) and Table 310.15(B)(19). Where cablebus are continuously covered for more than 1.8 m (6 ft) with solid unventilated covers, the ampacities for 1/0 AWG through 500 kcmil cables shall not exceed 60 percent of the allowable ampacities in Table 310.15(B)(17) and Table 310.15(B)(19).

(C) Ampacity of Type MV and Type MC Cables (2001 Volts or Over) in Cablebus. The ampacity of cables, rated 2001 volts, nominal, or over, installed according to 392.22(C) shall not exceed the requirements of this section.

(1) Single-Conductor Cables (2001 Volts or Over). The ampacity of single-conductor cables shall comply with the following:

(a) The ampacities for 1/0 AWG and larger single-conductor cables in ventilated cablebus shall not exceed 75 percent of the allowable ampacities in Table 310.60(C)(69) and Table 310.60(C)(70). Where the cablebus are covered for more than 1.8 m (6 ft) with solid unventilated covers, the ampacities for 1/0 AWG and larger single-conductor cables shall not exceed 70 percent of the allowable ampacities in Table 310.60(C)(69) and Table 310.60(C)(70).

Informational Note No. 1: See 110.14(C) for conductor temperature limitations due to termination provisions for installations up to and including 2000 volts.

Informational Note No. 2: See 110.40 for conductor temperature limitations due to termination provisions for installations 2001 to 35,000 volts.

Statement of Problem and Substantiation for Public Comment

The committee statement did address the proposal regarding the informational notes but does not appear to address the inconsistency between cablebus allowable ampacities and the allowable ampacities for cables in cable tray. I am asking the committee to reconsider this proposal intended to align cablebus allowable ampacities with the similar installation requirements in Article 392.80.

Article 372  Cellular Concrete Floor Raceways

372.1  Scope.
This article covers cellular concrete floor raceways, the hollow spaces in floors constructed of precast cellular concrete slabs, together with suitable metal fittings designed to provide access to the floor cells.

372.2  Definitions.
Cell.
A single, enclosed tubular space in a floor made of precast cellular concrete slabs, the direction of the cell being parallel to the direction of the floor member.

Header.
Transverse metal raceways for electrical conductors, providing access to predetermined cells of a precast cellular concrete floor, thereby permitting the installation of electrical conductors from a distribution center to the floor cells.

II Installations

372.4  Uses Not Permitted.
Conductors shall not be installed in precast cellular concrete floor raceways as follows:
(1) Where subject to corrosive vapor
(2) In any hazardous (classified) location, except as permitted by other articles in this Code
(3) In commercial garages, other than for supplying ceiling outlets or extensions to the area below the floor but not above

Informational Note: See 300.8 for installation of conductors with other systems.

372.5  Cellular Concrete Floor Raceways Installation.

(A) Header.
The header shall be installed in a straight line at right angles to the cells. The header shall be mechanically secured to the top of the precast cellular concrete floor. The end joints shall be closed by a metal closure fitting and sealed against the entrance of concrete. The header shall be electrically continuous throughout its entire length and shall be electrically bonded to the enclosure of the distribution center.

(B) Connection to Cabinets and Other Enclosures.
Connections from headers to cabinets and other enclosures shall be made by means of listed metal raceways and listed fittings.

(C) Junction Boxes.
Junction boxes shall be leveled to the floor grade and sealed against the free entrance of water or concrete. Junction boxes shall be of metal and shall be mechanically and electrically continuous with the header.

(D) Markers.
A suitable number of markers shall be installed for the future location of cells.

(E) Inserts.
Inserts shall be leveled and sealed against the entrance of concrete. Inserts shall be of metal and shall be fitted with grounded-type receptacles. A grounding conductor shall connect the insert receptacles to a positive ground connection provided on the header. Where cutting through the cell wall for setting inserts or other purposes (such as providing access openings between header and cells), chips and other dirt shall not be allowed to remain in the raceway, and the tool used shall be designed so as to prevent the tool from entering the cell and damaging the conductors.

(E) Markers.  A suitable number of markers shall be installed for the future location of cells.

372.10  Size of Conductors.
No conductor larger than 1/0 AWG shall be installed, except by special permission.
372.11 - Maximum Number of Conductors.

The combined cross-sectional area of all conductors or cables shall not exceed 40 percent of the cross-sectional area of the cell or header.

372.12 - Ampacity of Conductors.

The ampacity adjustment factors, provided in 310.15(B)(3), shall apply to conductors installed in cellular concrete floor raceways.

372.56 - Splices and Taps.

Splices and taps shall be made only in header access units or junction boxes. A continuous unbroken conductor connecting the individual outlets is not a splice or tap.

372.13 - Discontinued Outlets.

When an outlet is abandoned, discontinued, or removed, the sections of circuit conductors supplying the outlet shall be removed from the raceway. No splices or reinsulated conductors, such as would be the case of abandoned outlets on loop wiring, shall be allowed in raceways.

372.17 - Ampacity of Conductors.

The ampacity adjustment factors, provided in 310.15(B)(3), shall apply to conductors installed in cellular concrete floor raceways.

Statement of Problem and Substantiation for Public Comment

Reconsider Resolved Public Input #802 and revise Article 372. Common numbering of the sections within each of the raceway articles is considered to be beneficial and preferable. Per CMP-8 Resolution Statement, this Public Comment not only renumbers Section 372.4 for uses not permitted to 372.12 as proposed in Public Input #802, but renumbers the complete Article to align with the raceway numbering format. No text or requirements were revised.

Committee Statement

Committee Action: Accepted
Resolution: SR-2105-NFPA 70-2015
Statement: Common numbering of the sections within each of the raceway articles is considered to be beneficial and preferable. Per CMP-8 Resolution Statement, this Public Comment not only renumbers Section 372.4 for uses not permitted to 372.12 as proposed in Public Input #802, but renumbers the complete Article to align with the raceway numbering format. No text or requirements were revised.
See attached proposed Changes

**Article 374** Cellular Metal Floor Raceways

**Part I. General**

374.1 Scope.

This article covers the use and installation requirements for cellular metal floor raceways.

374.2 Definitions.

**Cellular Metal Floor Raceway.**

The hollow spaces of cellular metal floors, together with suitable fittings, that may be approved as enclosed channel for electrical conductors.

**Cell.**

A single enclosed tubular space in a cellular metal floor member, the axis of the cell being parallel to the axis of the metal floor member.

**Header.**

A transverse raceway for electrical conductors, providing access to predetermined cells of a cellular metal floor, thereby permitting the installation of electrical conductors from a distribution center to the cells.

**Part II. Installation**

374.312 Uses Not Permitted.

Conductors shall not be installed in cellular metal floor raceways as follows:

1. Where subject to corrosive vapor
2. In any hazardous (classified) location, except as permitted by other articles in this Code
3. In commercial garages, other than for supplying ceiling outlets or extensions to the area below the floor but not above

Informational Note: See 300.8 for installation of conductors with other systems.

374.4 Size of Conductors.

No conductor larger than 1/0 AWG shall be installed, except by special permission.

374.5 Maximum Number of Conductors in Raceway.

The combined cross-sectional area of all conductors or cables shall not exceed 40 percent of the interior cross-sectional area of the cell or header.

374.6 Splices and Taps.

Splices and taps shall be made only in header access units or junction boxes.

For the purposes of this section, so-called loop wiring (continuous unbroken conductor connecting the individual outlets) shall not be considered to be a splice or tap.

374.7 Discontinued Outlets.

When an outlet is abandoned, discontinued, or removed, the sections of circuit conductors supplying the outlet shall be removed from the raceway. No splices or reinsulated conductors, such as would be the case with abandoned outlets on loop wiring, shall be allowed in raceways.

374.8 Markers.

A suitable number of markers shall be installed for locating cells in the future.

374.9 Junction Boxes.

374.18 Cellular Metal Floor Raceways Installations.

Cellular Metal Floor Raceways installations shall comply with 374.18(A) through (D).

374.11 (A) Connection to Cabinets and Extensions from Cells.

Connections between raceways and distribution centers and wall outlets shall be made by means of liquidtight flexible metal conduit, flexible metal conduit where not installed in concrete, rigid metal conduit, intermediate metal conduit, electrical metallic tubing, or approved fittings. Where there are provisions for the termination of an equipment grounding conductor, rigid polyvinyl chloride conduit, reinforced thermosetting resin conduit, electrical nonmetallic tubing, or liquidtight flexible nonmetallic conduit shall be permitted. Where installed in concrete, liquidtight flexible metal conduit and liquidtight flexible nonmetallic conduit shall be listed and marked for direct burial.

374.9 (B) Junction Boxes.

Junction boxes shall be leveled to the floor grade and sealed against the free entrance of water.
or concrete. Junction boxes used with these raceways shall be of metal and shall be electrically continuous with the raceway.

374.

10. (C) Inserts.

Inserts shall be leveled to the floor grade and sealed against the entrance of concrete. Inserts shall be of metal and shall be electrically continuous with the raceway. In cutting through the cell wall and setting inserts, chips and other dirt shall not be allowed to remain in the raceway, and tools shall be used that are designed to prevent the tool from entering the cell and damaging the conductors.

374.

11. Connection to Cabinets and Extensions from Cells.

Connections between raceways and distribution centers and wall outlets shall be made by means of liquidtight flexible metal conduit, flexible metal conduit where not installed in concrete, rigid metal conduit, intermediate metal conduit, electrical metallic tubing, or approved fittings. Where there are provisions for the termination of an equipment grounding conductor, rigid polyvinyl chloride conduit, reinforced thermosetting resin conduit, electrical nonmetallic tubing, or liquidtight flexible nonmetallic conduit shall be permitted. Where installed in concrete, liquidtight flexible metal conduit and liquidtight flexible nonmetallic conduit shall be listed and marked for direct burial.

374.17. Ampacity of Conductors.

8. (D) Markers. A suitable number of markers shall be installed for locating cells in the future.

374.20. Size of Conductors. No conductor larger than 1/0 AWG shall be installed, except by special permission.

374.22. Maximum Number of Conductors in Raceway.

The combined cross-sectional area of all conductors or cables shall not exceed 40 percent of the interior cross-sectional area of the cell or header.

374.23. Ampacity of Conductors. The ampacity adjustment factors in 310.15(B)(3) shall apply to conductors installed in cellular metal floor raceways.

Part III.

374.56. Splices and Taps. Splices and taps shall be made only in header access units or junction boxes.

For the purposes of this section, so-called loop wiring (continuous unbroken conductor connecting the individual outlets) shall not be considered to be a splice or tap.

374.58. Discontinued Outlets. When an outlet is abandoned, discontinued, or removed, the sections of circuit conductors supplying the outlet shall be removed from the raceway. No splices or reinsulated conductors, such as would be the case with abandoned outlets on loop wiring, shall be allowed in raceways.

II. III. Construction Specifications

374.

100. General.

Cellular metal floor raceways shall be constructed so that adequate electrical and mechanical continuity of the complete system will be secured. They shall provide a complete enclosure for the conductors. The interior surfaces shall be free from burrs and sharp edges, and surfaces over which conductors are drawn shall be smooth. Suitable bushings or fittings having smooth rounded edges shall be provided where conductors pass.

Statement of Problem and Substantiation for Public Comment

This PI should have been a First Revision; this will make the NEC more users friendly by following an already established pattern that the .12 section of an article is uses permitted. This will also follow 2.4.1 of the NEC style manual. The committee statement; "Common numbering of the sections within each of the raceway articles is considered to be beneficial and preferable. However, renumbering of Section 374.3 for uses not permitted should be completed as part of a complete renumbering of Article 374." Renumbering is not necessary; there currently is not a .12 section of Article 374.

Support David Kendall's PC to renumber Article 374.3.

Committee Statement

Committee Action: Rejected
Resolution: The committee agrees that a common numbering method within the raceway articles is beneficial and preferable; however, simply renumbering Section 374.3 as 374.12 would result in the relocation of the “Uses Not Permitted” section after section 374.11 and would not achieve the goal of the commenter of making the Code more user friendly. See the Panel action and statement for PC # 423 which addresses the concerns of the submitter.
Public Comment No. 1223-NFPA 70-2015 [Section No. 376.56(B)(1)]

1) Installation.

Power distribution blocks installed in metal wireways shall be listed and labeled. Power distribution blocks installed on the line side of the service equipment shall be listed and identified for the purpose.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-2101-NFPA 70-2015
Statement: The Correlating Committee has appointed a Task Group to address the “Listed and Labeled” Public Inputs for the 2020 NEC. This issue needs correlation throughout the Code so that there is consistency. The use of a Task Group to achieve this is necessary. It is acceptable to wait for the 2020 NEC to properly address and correlate this issue since a safety hazard has not been identified in the substantiations of either the Public Input or Comment pertaining to conduit, tubings and fittings.

CMP-8 cannot accept “and labeled” until the definition of “Labeled” is addressed by the Task Group.

Power distribution blocks within metal wireway and used on the line side of the service equipment shall be identified acceptable for the use.
378.6 Listing Requirements.

Nonmetallic wireways and associated fittings shall be listed and labeled.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

Public Comment No. 659-NFPA 70-2015 [Section No. 384.6]

384.6 Listing Requirements.
Strut-type channel raceways, type closure strips — and accessories shall be listed, labeled, and identified for such use.

Statement of Problem and Substantiation for Public Comment

Channel is not considered a listed electrical raceway without the closure strip therefore only the fittings and closure strip will contain the listing mark.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacturer remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. Resolution: The Correlating Committee has appointed a Task Group to address the “Listed and Labeled” Public Inputs for the 2020 NEC. This issue needs correlation throughout the Code so that there is consistency. The use of a Task Group to achieve this is necessary. It is acceptable to wait for the 2020 NEC to properly address and correlate this issue since a safety hazard has not been identified in the substantiations. CMP-8 cannot accept “and labeled” until the definition of “Labeled” is addressed by the Task Group.
392.10(E) Airfield Lighting Cable Tray

In airport establishments, where conditions of maintenance and supervision ensure that only qualified persons, have access, install, or service the cable, airfield lighting cable used in series circuits rated up to 5000 volts and powered by constant current regulators shall be permitted to be installed in cable tray. The cable shall be FAA L-824 Type B or Type C cable.

Informational Note to 392.10(E): Federal Aviation Administration (FAA) Advisory Circulars (ACs) provide additional practices and methods for airport lighting.

Additional Proposed Changes

Statement of Problem and Substantiation for Public Comment

Primary circuit L-824 cable typically enters one side of the metallic (galvanized steel) light base through a conduit entry point and exits on the opposite side of the light base through a second/different entry (exit) point.

No inductive heating occurs in this application.

Inductive heating has never been a problem in airfield lighting circuits.

Typically both L-824 conductors of the series circuit are routed together in the airfield lighting vault. Therefore no inductive heating within the cable tray would occur.

I respectfully request the CMP re-examine PI-2739 and approve the use of FAA type L-824 cables in cable tray for locations accessible to qualified persons only.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-2107-NFPA 70-2015
Statement: The submitter has provided additional information to the CMP, along with substantiation that the proposed installation is in line with the intent of the Code, does not present a safety issue, and is consistent with industry means and methods.

Typically airfield lighting cables of the series circuit are routed together in the airfield lighting vault. Therefore no
inductive heating within the cable tray would occur.

CMP-8 re-examined PI-2739 and recognize the use of other types of cables in cable tray for locations accessible to qualified persons only.
392.10(E) Airfield Lighting Cable Tray

In airport establishments, where conditions of maintenance and supervision ensure that only qualified persons have access, install, or service the cable, airfield lighting cable used in series circuits rated up to 5000 volts and powered by constant current regulators shall be permitted to be installed in cable tray. The cable shall be FAA L-824 Type B or Type C cable.

Informational Note to 392.10(E): Federal Aviation Administration (FAA) Advisory Circulars (ACs) provide additional practices and methods for airport lighting.

Statement of Problem and Substantiation for Public Comment

Problem statement:

FAA L-824 cable is not specifically permitted to be installed in cable tray by the NEC. Some authorities having jurisdiction do not see equivalence in permitting MV cables and L-824 cables to be installed in cable tray in locations accessible only to qualified persons.

Substantiation:

FAA L-824 Type C cable has been installed in cable trays within airfield lighting vault buildings that have controlled access to qualified personnel only, in accordance with Article 300.37, for many decades. This is an industry standard practice. With regard to the use of cable trays, single phase inductive heating is not an issue for two reasons. First of all, airfield lighting series circuits are limited to a maximum of 6.6 amperes for new designs and 20 amperes for maintenance of legacy systems that have not been updated to more efficient lighting technologies. Secondly, within airfield lighting vaults both conductors of the series circuit (feed and return conductors) are run together within raceways and cable trays from the point of entry to the constant current regulator. This mitigates any concern of single phase inductive heating.

### Statement of Problem and Substantiation for Public Comment

A typical airfield lighting series circuit for a runway at a General Aviation Airport may be 20,000 feet long (made up of 20,000 linear feet of L-824 cable). The circuit would originate at the airfield lighting vault, be routed out to and around the runway and then return to the airfield lighting vault. In addition to the lights, the circuit would probably power a couple of wind cones and all the runway signs as well.

At an Air Carrier Airport the circuit could be 40,000 feet long. It would be reasonable to accept that all constant current regulators (CCR = power source for the airfield lighting series circuit) are within 50 feet of the underground circuit entry into the airfield lighting vault.

Outside the vault, all L-824 cable would be installed in underground raceways, pull boxes, manholes, light bases, etc. Assuming a maximum of 50 feet to the CCR a maximum of 100 feet of L-824 cable (less than 1%) per circuit would be installed in the cable tray. The installation of L-824 cable in cable tray is a very minimal application for the L-824 airfield lighting cable. The narrow limited application would be for use inside the airfield lighting vault. Access to the airfield lighting vault is limited to qualified persons.

L-824 cables installed in cable tray provide ready access and the necessary flexibility for troubleshooting, cable replacement, and to move the cables to the spare constant current regulator, thus expediting the repairs or cable replacement and enhancing the safety of the flying public.

I respectfully request the CMP re-examine PI-2739 and approve the use of FAA type L-824 cables in cable tray for locations accessible to qualified persons only.

(D) Nonmetallic Cable Tray.

In addition to the uses permitted elsewhere in 392.10, nonmetallic cable tray shall be permitted in corrosive areas and in areas requiring voltage isolation.

Statement of Problem and Substantiation for Public Comment

Public Input No. 2739-NFPA 70-2014 (New Section after No. 392.10 (D))

- Comments to Substantiation commentary from Carl Johnson – Avcon10/28/14

Section No. 392.10(D) discusses the application and protection of L824 cables that are used to power airfield lights. The system is set up such that Edison Power, which is voltage controlled is brought into a vault on the airfield. The Edison power goes through switchgear to transform to airfield application needs and then is transformed via a plurality of constant current regulators to deliver power to airfield circuits that are current controlled in series. The constant current regulator is used to control current at specified steps or intensities to control the brightness of the lights on the airfield depending on varying visibility conditions. Each constant current regulator typically controls the lighting for a designated geographic area on the airfield (ie, Taxiway A Edge Lights, Runway 18 Centerline Lights, Runway 27 Edge Lights, Runway 9 Threshold Lights, etc.).

The airfield vault houses the switchgear and constant current regulator units and is similar to an electrical substation. It is the key area and acts as the brain of the airfield lighting system. Therefore, it is very important that the equipment is maintained and serviced to the highest quality standards to support the effective lighting of an airfield, which is critical to aircraft and personal safety.

It is a very controlled area. Only authorized personnel are allowed in the airfield vault for monitoring or maintenance needs. Carl Johnson II discusses some of those needs in his post from 10/28/14. The point I want to highlight is the criticality of timeliness of completion of those tasks. If there are issues that need to be diagnosed and tested on an airfield, the vault, regulators and their fed circuits must be accessed quickly and resolutions employed right away to prevent an unsafe airport operation.

Section No. 392.10 (D) addresses the safety of access to L824 cables throughout the airfield environment which is open to many contractors and construction personnel as they work on electrical systems. The code discusses how L824 cables are not permitted in cable trays. This is good sound practice throughout the outside airfield environment. However, access to and in the vault is more controlled and procedures are validated and audited. Further, the equipment in the vault must be readily accessible to authorized personnel to properly maintain and control with timely solutions in an effort to protect the safety of everyone in an airfield environment that uses airfield lighting to transport passengers via aircraft.

It is critically important that authorized personnel have readily available access to L824 cables and those cables should be permitted to be installed in cable trays in the airfield lighting vault only.

Public Comment No. 1156-NFPA 70-2015 [New Section after 392.80(A)]

Informational Note:
See 110.14(C) for conductor temperature limitations due to termination provisions.

Statement of Problem and Substantiation for Public Comment

Consistency of NEC language among similar sections is critical to understanding and enforcement of the requirements. Inconsistent language results in confusion for NEC users and difficulty for the AHJ community that must enforce the NEC rules. CMP 8 received (3) identical Public Inputs yet resolved two while creating a First Revision for the third. CMP 8 resolved PI 1466 and PI 1449 with the following committee statements:

The Code is not Intended to be an instruction manual for untrained persons. The substantiation to align the wording with another section will open the door to adding this type of Note to an inordinate number of other Articles.

PI 1448 resulted in First Revision 2154 with the following committee statement:

This revision clarifies the section by informing the user of additional provisions which may be applicable. It aligns this article with similar provisions in 310.15(A)(2) and 310.60(A)(1).

The actions and committee statements by CMP 8 were inconsistent among the (3) Public Inputs. The addition of the proposed Informational Note after Section 392.80(A) does not result in creation of an instruction manual and is essential for Code users and enforcers as indicated by the committee statement for PI 1448.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-7506-NFPA 70-2015
Statement: This revision clarifies the section by informing the user of additional provisions which may be applicable. It aligns this article with similar requirements in 310.15(A)(2) and 310.60(A)(1).
Public Comment No. 1145-NFPA 70-2015 [ New Section after 392.80(B)(2) ]

Informational Note:
Informational Note: See 110.40 for conductor temperature limitations due to termination provisions.

Statement of Problem and Substantiation for Public Comment

Consistency of NEC language among similar sections is critical to understanding and enforcement of the requirements. Inconsistent language results in confusion for NEC users and difficulty for the AHJ community that must enforce the NEC rules. CMP 8 received (3) identical Public Inputs yet resolved two while creating a First Revision for the third.

CMP 8 resolved PI 1466 and PI 1449 with the following committee statements:

The Code is not Intended to be an instruction manual for untrained persons. The substantiation to align the wording with another section will open the door to adding this type of Note to an inordinate number of other Articles.

PI 1448 resulted in First Revision 2154 with the following committee statement:

This revision clarifies the section by informing the user of additional provisions which may be applicable. It aligns this article with similar provisions in 310.15(A)(2) and 310.60(A)(1).

The actions and committee statements by CMP 8 were inconsistent among the (3) Public Inputs. The addition of the proposed Informational Note after Section 392.80(B) does not result in creation of an instruction manual and is essential for Code users and enforcers as indicated by the committee statement for PI 1448.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacturer remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL

Additional Proposed Changes

Committee Statement

Committee Action: Accepted
Resolution: SR-5103-NFPA 70-2015
Statement:
The Panel agrees with public comment clarifying certain equipment be “listed and labeled” instead of just “listed.” Qualified Electrical Testing Laboratories do not consider a product to be listed unless the label has actually been applied.

Additionally, the Article 100 definition for “labeled” includes the provision for labeling the smallest unit carton for parts which are too small to include the listing mark on the parts themselves. Labeling includes listing marks that are stamped or molded on or into the product.
Public Comment No. 144-NFPA 70-2015 [Section No. 396.2]

396.2 Definitions.

Insulated Conductor.
For the purposes of this article, an insulated conductor includes those listed in Article 310 and conductors encased in a polymeric material that has been evaluated for the applied nominal voltage.

Informational Note: Evidence of evaluation for the applied nominal voltage can be given by certification that the conductors have met the requirements of ICEA S-76-474-2004 2011, Standard for Neutral Supported Power Cable Assemblies with Weather-Resistant Extruded Insulation Rated 600 Volts.

Messenger-Supported Wiring.
An exposed wiring support system using a messenger wire to support insulated conductors by any one of the following:

1. A messenger with rings and saddles for conductor support
2. A messenger with a field-installed lashing material for conductor support
3. Factory-assembled aerial cable
4. Multiplex cables utilizing a bare conductor, factory assembled and twisted with one or more insulated conductors, such as duplex, triplex, or quadruplex type of construction

Statement of Problem and Substantiation for Public Comment

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-1814-NFPA 70-2015
Statement: Since the conductors that are not included in 310.104 do not have flame retardants, the panel revised the language to limit the application of this wiring method to overhead service conductors. Overhead service conductors are permitted to be insulated or covered in 230.22, thereby correlating the use of Article 396 with the requirements in Article 230.
396.2 Definitions.

Insulated Conductor.
For the purposes of this article, an insulated conductor includes those listed in Article 310 and conductors encased in a polymeric material that has been evaluated for the applied nominal voltage.

Informational Note: Evidence of evaluation for the applied nominal voltage can be given by certification that the conductors have met the requirements of ICEA S-76-474-2004, Standard for Neutral Supported Power Cable Assemblies with Weather-Resistant Extruded Insulation Rated 600 Volts.

Messenger-Supported Wiring.
An exposed wiring support system using a messenger wire to support insulated conductors by any one of the following:

(1) A messenger with rings and saddles for conductor support
(2) A messenger with a field-installed lashing material for conductor support
(3) Factory-assembled aerial cable
(4) Multiplex cables utilizing a bare conductor, factory assembled and twisted with one or more insulated conductors, such as duplex, triplex, or quadruplex type of construction

Statement of Problem and Substantiation for Public Comment

The proposed new definition is not appropriate for the NEC. As clearly stated in the first sentence of the substantiation for PI 2289, this is all about "service drop applications." See 90.2. The intent of the proposed new definition and informational note is to recognize messenger supported cable for use on the load side of the service point. This will create serious safety concerns.

The substantiation provided by CMP-7 is lacking in substance. The statement simply states that "This definition is necessary to recognize commonly used wiring methods for messenger-supported." CMP-7 provided no technical substantiation as required to change the code. This is most likely due to the fact that there is no technical substantiation to support this new definition and informational note. In fact, technical substantiation exists in abundance to reject this proposed revision.

The substantiation in PI 2289 stated that non-listed, uninsulated triplex and quadplex is "identified" for "the use." What "use" and how was the product "identified"? Who stood behind such a serious statement? The informational note that accompanies the definition of "identified" in Article 100 provides the code user with information on how a given product may be recognized as "identified." These products are not "listed or labeled." There are no inspection agencies or other organizations concerned with product evaluation getting behind such an effort.

As used by electric utilities for service drops these products serve an extremely useful purpose. That purpose ends at the service point. The proposed definition is in direct conflict with the existing definition of "messenger-supported wiring" which clearly requires "insulated conductors" where a multiplex cable is used. There is significant reason that these products are not listed. They have zero physical damage properties. These products cut as easily as skin in the heat of the summer and they shatter on impact in sub freezing temperatures.

See CFR 29 1926.403(a) which requires electrical products used in construction (temporary wiring) to be "approved". The term "approved" as used in this OSHA requirement follows:

Approved. Acceptable to the authority enforcing this Subpart. The authority enforcing this Subpart is the Assistant Secretary of Labor for Occupational Safety and Health. The definition of "acceptable" indicates what is acceptable to the Assistant Secretary of Labor, and therefore approved within the meaning of this Subpart.

The term acceptable is defined in this subpart as follows:
Acceptable. An installation or equipment is acceptable to the Assistant Secretary of Labor, and approved within the meaning of this Subpart:
(a) If it is accepted, or certified, or listed, or labeled, or otherwise determined to be safe by a qualified testing laboratory capable of determining the suitability of materials and equipment for installation and use in accordance with this standard; or
(b) With respect to an installation or equipment of a kind which no qualified testing laboratory accepts, certifies, lists, labels, or determines to be safe, if it is inspected or tested by another Federal agency, or by a State, municipal, or other local authority responsible for enforcing occupational safety provisions of the National Electrical Code, and found in compliance with those provisions; or
(c) With respect to custom-made equipment or related installations which are designed, fabricated for, and intended for use by a particular customer, if it is determined to be safe for its intended use by its manufacturer on the basis of test data which the employer keeps and makes available for inspection to the Assistant Secretary and his authorized representatives.

No qualified testing laboratory has accepted, certified, listed, labeled, or otherwise determined these products as safe for use in construction or otherwise.
Use of these products is not "one of a kind", nor is it custom made.
Use of these products for temporary violates the OSHA standards for good reason. Listed products such as types SE and SER are
readily available, insulated, covered and listed.

Adding a definition of "insulated" that recognizes a covered conductor as "insulated" is a slippery slope for the NEC.

There is no practical or technical reason to support such a revision. This proposed revision would seriously impact safety.

Submitter Information Verification
Submitter Full Name: Aaron Adamczyk
## Committee Statement

**Committee Action:** Accepted  
**Resolution:** SR-1815-NFPA 70-2015  
**Statement:** The changes in this comment are consistent with the current name of the document referenced.
**Public Comment No. 446-NFPA 70-2015 [Section No. 400.1]**

400.1 Scope.
This article covers general requirements, applications, and construction specifications for flexible cords and flexible cables.

Informational Note: UL 817, Cord Sets and Power-Supply Cords, allows the use of flexible cords manufactured in accordance with UL 62, Flexible Cords and Cables. Cord sets and power-supply cords are restricted in use by the requirements in Article 400.

Statement of Problem and Substantiation for Public Comment

Informational notes are just that a note, they can't contain a NEC requirement. Clearly Article 400 applies to Flexible Cords and Cables as constructed in accordance with UL 62. If the panel wants to expand the scope of Article 400 to include Cord Sets (extension cords) and Power Supply Cords which are constructed per UL 817, then the title of Article 400 needs to read. Article 400. Flexible Cords, Flexible Cables, Cord Sets, and Power Supply Cords. In addition, the scope of Article 400 in 400.1 needs to also be revised to include UL 817 products.

The 'reach' by the panel to require extension cords and power supply cords on listed products to comply with the "installation" requirements of the NEC (via an Informational Note) will result in significant conflict in the 'use' of listed products. I feel the TCC should direct the panel to delete this Information Note as written, since it's attempts to wire a 'rule' within an Informational Note.

**Committee Statement**

Committee Action: Rejected but see related SR
Resolution: SR-1503-NFPA 70-2015
Statement: The code does not presently advise that cords used in listed cord sets and power supply cords need to meet the same installation requirements as flexible cords in article 400. The informational note was included to advise that flexible cords used in listed cord sets and power supply cords are covered by this article.
Statement of Problem and Substantiation for Public Comment

Milestone AV Technologies LLC and other manufacturers are supplying metal ceiling enclosures for housing AV and ITE/communications equipment. An example of AV equipment would be a HDMI scaler and of ITE/communications equipment would be an Ethernet switch/hub or a WI-FI access point and antenna.

Although these enclosures are by definition located above the surface of the suspended or dropped ceiling, if they are Listed to ANSI/UL 2043-2008 for use in Other Spaces Used for Environmental Air, they are isolated from and not in the above ceiling environmental space per se. They typically have power outlets within them and the flexible cords and cables for the equipment installed in them stay totally within the enclosure. Therefore in this application, the flexible cords and cables do not run through the above ceiling space. You could install this same enclosure in a “hard ceiling” and it would comply with 400.8(5). There is no difference with regard to flexible cords and cables in this application above a suspended or dropped ceiling.

Committee Statement
Resolution: This type of equipment is already listed for use in Other spaces Used for Environmental Air and does not require specific allowance in 400.7.

Problem

It appears that the committee thought that having the enclosure Listed for use in the environmental air space, that flexible cords inside of it shouldn’t be a problem, however this has been an ongoing enforcement issue with our products.

Even though the enclosure is a Listed enclosure for environmental air space, AHJ’s are rejecting the installation because of the wording in the NEC. This addition will help clarify this use.

Related Item
Public Input No. 1070-NFPA 70-2014 [New Section after 400.7(A)]
400.12 Uses Not Permitted.

Unless specifically permitted in 400.10, flexible cables, flexible cord sets, and power supply cords shall not be used for the following:

(1) As a substitute for the fixed wiring of a structure
(2) Where run through holes in walls, structural ceilings, suspended ceilings, dropped ceilings, or floors
(3) Where run through doorways, windows, or similar openings
(4) Where attached to building surfaces

   Exception to (4): Flexible cord and cable shall be permitted to be attached to building surfaces in accordance with 368.56(B) for branches from busways and receptacle pendants.

(5) Where concealed by walls, floors, or ceilings or located above suspended or dropped ceilings
(6) Where installed in raceways, except as otherwise permitted in this Code
(7) Where subject to physical damage

Statement of Problem and Substantiation for Public Comment

The Exception to 400.12(A)(4) (former Ex. to 400.8(B)(4)) has been a topic of discussion at many meetings and there are always mixed opinions on how to interpret “in accordance with 368.56(B).” Some read it literally and only allow it for branches from busways and others recognize the methods described in 368.56 for a cord type pendant from a wireway or junction box for a pendant receptacle outlet. The methods described in 368.56 have been used for installing cord pendant drops that do not originate from a busway for many years without incident. Therefore there is no practical reason to limit the installation methods described in 368.56 to just branches that originate at a busway.

I am aware of an industrial application where wireways were suspended using strut type frames and used for supplying cord type pendant drops for receptacle outlets. The cords were connected to the bottom of the wireways with gland type strain relief connectors. The cords then ran less than 1.8 m (6 ft.) to a suitable tension take up device and then down to the work stations below. The company was cited for violating 368.56 and instructed to remove over 100 take up devices and let the cords hang directly from the gland type strain relief connectors. If that is not the intent of the current exception, the proposed revision would add clarity. Additional clarity could be added by removing the word “receptacle” from in front of “pendants” if the desire is not to limit the application to just receptacle pendants.

State:
Zip:
Submittal Date: Fri Sep 25 11:43:16 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The exception already references section 368.56 that covers busways, however, there is no reference to receptacle pendants in section 368.56. Straight pendants are allowed by Article 400.10(A)(1). Wireways are not covered under Article 368.
400.12 Uses Not Permitted.

Unless specifically permitted in 400.10, flexible cables, flexible cord sets, and power supply cords shall not be used for the following:

1. As a substitute for the fixed wiring of a structure
2. Where run through holes in walls, structural ceilings, suspended ceilings, dropped ceilings, or floors
3. Where run through doorways, windows, or similar openings
4. Where attached to building surfaces
   
   Exception to (4): Flexible cord and cable shall be permitted to be attached to building surfaces in accordance with 368.56(B).

5. Where concealed by walls, floors, or ceilings or located above suspended or dropped ceilings
6. Where installed in raceways, except as otherwise permitted in this Code
7. Where subject to physical damage

Statement of Problem and Substantiation for Public Comment

Delete revised text and bring back to 2014. Section 400.8 applies to flexible cords [UL 62] (so add 'flexible cords' that back) and since the scope of Article 400 does not apply to cords sets (extension cords) or power supply [UL 817], delete 'flexible cord sets and power supply cords.'

The NEC is an 'installation' standard not a 'use standard. The NEC has no right to govern how I personally use extension cords or power supply cords. This is governed by the Fire Code, not the NEC.

Committee Statement

Committee Action: Rejected
Resolution: Section 400.10(B) references uses permitted for cords in cord sets and power supply cords. The first revision wording of Section 400.12 is needed to advise of uses that are not permitted as it pertains to the cord within a cord set or power supply cord.
Switches Controlling Lighting Loads.

The grounded circuit conductor for the controlled lighting circuit shall be installed at the location where switches control lighting loads that are supplied by a grounded general-purpose branch circuit for bathrooms, hallways, stairways, or a room suitable for human habitation or other occupancy as defined in the applicable building code. A grounded conductor shall not be required to be installed at lighting switch locations under any of the following conditions:

1. Where conductors enter the box enclosing the switch through a raceway, provided that the raceway is large enough for all contained conductors, including a grounded conductor

2. Where the box enclosing the switch is accessible for the installation of an additional or replacement cable without removing finish materials

3. Where snap switches with integral enclosures comply with 300.15(E)

4. Where a switch serves other than a bathroom, hallway, stairway, or a room suitable for human habitation or other occupancy as defined in the applicable building code

5. Where multiple switch locations control the same lighting load such that the entire floor area of the room or space is visible from the single or combined switch locations, the grounded circuit conductor shall only be required at one location.

6. Where lighting in the area is controlled by automatic means

7. Where a switch controls a receptacle load

Informational Note: The provision for a (future) grounded conductor is to complete a circuit path for electronic lighting control devices.

Statement of Problem and Substantiation for Public Comment

Relocating (4) into the parent rule would make it easier to apply the requirement.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-2408-NFPA 70-2015
Statement: This action fully supports the concept that the grounded conductor of the lighting circuit must not only be available for connection to an electronic switch, it must be actually connected to the device. In addition, and particularly in instances wired in accordance with list item #2, it must be extended through the relevant raceway to the switch location in order to permit the required connection. This requirement has been formatted as a stand-alone paragraph in this section in order to clearly address field wiring issues that do not belong in Part II of this Article.

The principal change in this part of the Code is a new exception that addresses the circumstances under which previous switch designs and connection protocols that assumed up to 0.5 mA of neutral current could be allowed to flow over an equipment grounding return path might continue to be used safely. These switches have been used for decades with no reported loss experience, but as they continue to proliferate ever increasing current loading will be imposed on a system that is not and never will be designed for routing load current. Since the advent of the 2011 NEC, CMP 9 has been moving in a direction that limits the usage of these switches hoping to avoid an eventual problem.

At the first revision stage, CMP 9 placed a sunset date of January 1, 2020 on the use of these switches in what will be
404.22. In response, three comments (#1256, #485, #832) supported a continuing retrofit allowance under the old protocol and one (#770) asked for an immediate termination of acceptability. CMP 9 reaffirms the 2020 sunset date as the default limit, but agrees that based on the historical record some continuation of older designs is warranted.

To this end, CMP 9 agrees to a replacement/retrofit limitation on the older designs, and also to numerical limits that effectively limit the worst-case neutral current that the equipment grounding system would be expected to carry to 2.5 mA on the smaller branch circuit conductors, and 12.5 mA on feeders. Since the original first revision stage action placed an extinction date on the older style devices where there was none previously, this action, which allows numerical limits instead of none at all, therefore should not be considered new material.

This concept is being addressed here in Part I because it will be an installation limitation; the listing and marking requirement is being covered in a correlating exception in what will be 404.22. Because this location will be the principal coverage of wiring issues in this regard, CMP 9 is including language disallowing the use of older designs, which will be inherently limited to existing applications, in the event that the return path in a panelboard includes a path through a panelboard enclosure as disallowed in 200.2(B). CMP 9 notes that this defect can be readily rectified in the field. CMP 9 is also including a clarification that a busbar carrying both equipment grounding and neutral terminations, as is permitted in service equipment, can support an indefinite number of these devices just as the number of allowable neutral connections are not limited, except inherently by the number of connection provisions.

The action on this comment also addresses three editorial issues, two of which were raised in public comments (#463 and #504) with which the panel is in substantive agreement. CMP 9 has removed from the list items the habitation/occupancy text (current item #4) and the multiple switch location text (current item #5) and inserted this material into the parent text where it improves readability. In addition, the parent text location leaves the new second paragraph standing alone where it will not be confused with requirements addressing where a grounded circuit conductor must be routed for normal installations in new work.

The third issue involves a minor error introduced in the first revision stage with respect to the wording of the habitation/occupancy text. It removes the word “other” ahead of “occupancy” in what now stands as list item four. The phrase should read "human habitation or occupancy" because a reference to "other occupancy" creates the unwanted implication that a switch in any other occupancy defined in the building code wherever located gets the neutral. In effect, it creates the implication that the word is being used as a noun. When a building code refers to an occupancy, it is referring to a species of building purpose, such as an assembly occupancy or an industrial occupancy. On the contrary, for this usage it is intended as a second object of the proposition "for" and needs to be used in an exactly parallel way to "for human habitation". The simplest way to accomplish this is to simply word the phrase "suitable for human habitation or occupancy".
Switches Controlling Lighting Loads.

The grounded circuit conductor for the controlled lighting circuit shall be installed at the location where switches control lighting loads that are supplied by a grounded general-purpose branch circuit. A grounded conductor shall not be required to be installed at lighting switch locations under any of the following conditions:

1. Where conductors enter the box enclosing the switch through a raceway, provided that the raceway is large enough for all contained conductors, including a grounded conductor.
2. Where the box enclosing the switch is accessible for the installation of an additional or replacement cable without removing finish materials.
3. Where snap switches with integral enclosures comply with 300.15(E).
4. Where a switch serves other than a bathroom, hallway, stairway, or a room that is not suitable for human habitation or other occupancy as defined in the applicable building code.
5. Where lighting in the area is controlled by automatic means.
6. Where a switch controls a receptacle load.

Where multiple switch locations control the same lighting load such that the entire floor area of the room or space is visible from the single or combined switch locations, the grounded circuit conductor shall only be required at one location.

Informational Note: The provision for a (future) grounded conductor is to complete a circuit path for electronic lighting control devices.

Statement of Problem and Substantiation for Public Comment

It seems list item 4 is a direct conflict to the intent of the section. Here's an example or two of the conflict created by double negatives:

1. A grounded conductor shall not be required to be installed at lighting switch locations under any of the following conditions:
   - Where a switch serves a living room
   - Where a switch serves a dining room
   - Where a switch serves a kitchen
   - Where a switch serves a recreation room
   - Where a switch serves a room suitable for human habitation or other occupancy as defined in the applicable building code.
   
   Also, it seems list item 5 should be a stand-alone paragraph that follows the list as it contains a special condition where a single grounded conductor IS required so this sentence does not fit in the list.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-2408-NFPA 70-2015
Statement: This action fully supports the concept that the grounded conductor of the lighting circuit must not only be available for connection to an electronic switch, it must be actually connected to the device. In addition, and particularly in instances wired in accordance with list item #2, it must be extended through the relevant raceway to the switch location in order to permit the required connection. This requirement has been formatted as a stand-alone paragraph in this section in order to clearly address field wiring issues that do not belong in Part II of this Article.
The principal change in this part of the Code is a new exception that addresses the circumstances under which previous switch designs and connection protocols that assumed up to 0.5 mA of neutral current could be allowed to flow over an equipment grounding return path might continue to be used safely. These switches have been used for decades with no reported loss experience, but as they continue to proliferate ever increasing current loading will be imposed on a system that is not and never will be designed for routing load current. Since the advent of the 2011 NEC, CMP 9 has been moving in a direction that limits the usage of these switches hoping to avoid an eventual problem.

At the first revision stage, CMP 9 placed a sunset date of January 1, 2020 on the use of these switches in what will be 404.22. In response, three comments (#1256, #485, #832) supported a continuing retrofit allowance under the old protocol and one (#770) asked for an immediate termination of acceptability. CMP 9 reaffirms the 2020 sunset date as the default limit, but agrees that based on the historical record some continuation of older designs is warranted.

To this end, CMP 9 agrees to a replacement/retrofit limitation on the older designs, and also to numerical limits that effectively limit the worst-case neutral current that the equipment grounding system would be expected to carry to 2.5 mA on the smaller branch circuit conductors, and 12.5 mA on feeders. Since the original first revision stage action placed an extinction date on the older style devices where there was none previously, this action, which allows numerical limits instead of none at all, therefore should not be considered new material.

This concept is being addressed here in Part I because it will be an installation limitation; the listing and marking requirement is being covered in a correlating exception in what will be 404.22. Because this location will be the principal coverage of wiring issues in this regard, CMP 9 is including language disallowing the use of older designs, which will be inherently limited to existing applications, in the event that the return path in a panelboard includes a path through a panelboard enclosure as disallowed in 200.2(B). CMP 9 notes that this defect can be readily rectified in the field. CMP 9 is also including a clarification that a busbar carrying both equipment grounding and neutral terminations, as is permitted in service equipment, can support an indefinite number of these devices just as the number of allowable neutral connections are not limited, except inherently by the number of connection provisions.

The action on this comment also addresses three editorial issues, two of which were raised in public comments (#463 and #504) with which the panel is in substantive agreement. CMP 9 has removed from the list items the habitation/occupancy text (current item #4) and the multiple switch location text (current item #5) and inserted this material into the parent text where it improves readability. In addition, the parent text location leaves the new second paragraph standing alone where it will not be confused with requirements addressing where a grounded circuit conductor must be routed for normal installations in new work.

The third issue involves a minor error introduced in the first revision stage with respect to the wording of the habitation/occupancy text. It removes the word “other” ahead of “occupancy” in what now stands as list item four. The phrase should read “human habitation or occupancy” because a reference to “other occupancy” creates the unwanted implication that a switch in any other occupancy defined in the building code wherever located gets the neutral. In effect, it creates the implication that the word is being used as a noun. When a building code refers to an occupancy, it is referring to a species of building purpose, such as an assembly occupancy or an industrial occupancy. On the contrary, for this usage it is intended as a second object of the proposition “for” and needs to be used in an exactly parallel way to “for human habitation”. The simplest way to accomplish this is to simply word the phrase “suitable for human habitation or occupancy”.

Switches Controlling Lighting Loads.

The grounded circuit conductor for the controlled lighting circuit shall be installed at the location where switches control lighting loads that are supplied by a grounded general-purpose branch circuit. The grounded conductor shall be connected to switching devices that require line-to-neutral voltages to operate the electronics of the switch in the standby mode, and shall meet the requirements in 404.22. A grounded conductor shall not be required to be installed at lighting switch locations under any of the following conditions:

1. Where conductors enter the box enclosing the switch through a raceway, provided that the raceway is large enough for all contained conductors, including a grounded conductor.
2. Where the box enclosing the switch is accessible for the installation of an additional or replacement cable without removing finish materials.
3. Where snap switches with integral enclosures comply with 300.15(E).
4. Where a switch serves other than a bathroom, hallway, stairway, or a room suitable for human habitation or other occupancy as defined in the applicable building code.
5. Where multiple switch locations control the same lighting load such that the entire floor area of the room or space is visible from the single or combined switch locations, the grounded circuit conductor shall only be required at one location.
6. Where lighting in the area is controlled by automatic means.
7. Where a switch controls a receptacle load.

Informational Note: The provision for a (future) grounded conductor is to complete a circuit path for electronic lighting control devices.

Statement of Problem and Substantiation for Public Comment

CMP-9 did a nice job of adding new section 404.22 that prohibits current from being introduced in the equipment grounding conductor from electronic switching devices. This comments seeks to build on the additional concerns expressed in the substantiation with Public Input 1375. The substantiation pointed out that there is still no requirement for connection of the required grounded conductor. This new language will provide installers with a clear requirement that if the install an electronic device that requires a line-to-neutral voltage to run the brain of the device, that it shall be connected to the device, and not just left safe-ended in the switch box. The reference from this section to new 404.22 will provide the additional restriction of current being introduced in the equipment grounding conductor, which was the revision sought by the original public input.

Public Comment No. 465-NFPA 70-2015 [Section No. 404.9(B)]

(B) Grounding.
Snap switches, including dimmer and similar control switches, shall be connected to an equipment grounding conductor and shall provide a means to connect metal faceplates to the equipment grounding conductor, whether or not a metal faceplate is installed. Metal faceplates shall be grounded. Snap switches shall be considered to be part of an effective ground-fault current path if either of the following conditions is met:

1. The switch is mounted with metal screws to a metal box or metal cover that is connected to an equipment grounding conductor or to a nonmetallic box with integral means for connecting to an equipment grounding conductor.
2. An equipment grounding conductor or equipment bonding jumper is connected to an equipment grounding termination of the snap switch.

Exception No. 1 to (B): Where no means exists within the snap-switch enclosure for connecting to the equipment grounding conductor, or where the wiring method does not include or provide an equipment grounding conductor, a snap switch without a connection to an equipment grounding conductor shall be permitted for replacement purposes only. A snap switch wired under the provisions of this exception and located within 2.5 m (8 ft) vertically, or 1.5 m (5 ft) horizontally, of ground or exposed grounded metal objects shall be provided with a faceplate of nonconductive noncombustible material with nonmetallic attachment screws, unless the switch mounting strap or yoke is nonmetallic or the circuit is protected by a ground-fault circuit interrupter.

Exception No. 2 to (B): Listed kits or listed assemblies shall not be required to be connected to an equipment grounding conductor if all of the following conditions are met:

1. The device is provided with a nonmetallic faceplate that cannot be installed on any other type of device,
2. The device does not have mounting means to accept other configurations of faceplates,
3. The device is equipped with a nonmetallic yoke, and
4. All parts of the device that are accessible after installation of the faceplate are manufactured of nonmetallic materials.

Exception No. 3 to (B): A snap switch with integral nonmetallic enclosure complying with 300.15(E) shall be permitted without a connection to an equipment grounding conductor.

Statement of Problem and Substantiation for Public Comment

Delete the text that the metal faceplate must be 'grounded' since this means that we need to run a wire from the metal plate to a ground rod or other approved electrode. The use of the terms 'ground, grounded, grounding, bond, bonded, and bonding' was fixed in in the 2008 NEC. This panel clearly doesn't understand the proper term to use. Since there is no problem as the 2014 is written, I suggest we keep this rule 'as is.'

Submittal Date: Sun Aug 30 14:15:31 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: CMP-9 is very familiar with terminology commonly used with grounding and bonding installations. CMP-9 used the term "grounded" as this was the term suggested by the submitter of PI 2300. The term "grounded" is the proper term here as the definition for "grounded" includes "connected (connecting) to ground or to a conductive body that extends the ground connection." In this case, the equipment grounding conductor would be this conductive body that extends the ground connection.
Public Comment No. 1256-NFPA 70-2015 [Section No. 404.22]

404.22 Electronic Lighting Control Switches.
Electronic lighting control switches shall be listed. They shall not introduce current on the equipment grounding conductor during normal operation. The requirement to not introduce current on the equipment grounding conductor shall take effect on January 1, 2020. For existing installations where the grounded conductor has not been provided in the switchbox, and where it is not practical to install a grounded conductor, electronic lighting control switches which introduce current on the equipment grounding conductor shall be permitted. These Electronic lighting control switches shall be listed and labeled for use in replacement or retrofit applications when configured such that they introduce current on the equipment grounding conductor.

Statement of Problem and Substantiation for Public Comment

Acuity Brands Lighting agrees with the comments submitted with the negative ballots from UL and NEMA. When an installation predates the required grounded conductor at switch locations, provisions should be made in the code to allow the use of energy saving products that have been evaluated and listed for this purpose. These products have been in use for years and are limited by the listing standard to no more than 0.5ma being introduced on the equipment grounding conductor. We manufacturer listed electronic lighting control switches that have a convertible design; they can be field configured for either connection to the grounded circuit conductor, or for connection to the equipment grounding conductor as shown in the attached illustration. When connected to the grounded conductor no current is introduced on the equipment grounding conductor. When connected to the equipment grounding conductor, the introduced current is less than 0.5ma.

Committee Action: Rejected but see related SR
Resolution: SR-2409-NFPA 70-2015
Statement: This new exception correlates with language placed in 404.2(C) pursuant to SR 2408. It contains only the provisions that are appropriate for the conditions that will apply to the manufacture and listing of electronic switches. It provides relief to the default requirement to sunset the acceptability of these older-designed switches in 2020. They will continue to be acceptable for replacement/retrofit applications into the future, provided they are listed accordingly. The marking requirement will assure that such devices, although listed, will not to be permitted for new work.
Electronic Lighting Control Switches.

Electronic lighting control switches shall be listed. They shall not introduce current on the equipment grounding conductor during normal operation. The requirement to not introduce current on the equipment grounding conductor shall take effect on January 1, 2020.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs that further consideration be provided to the comments expressed in voting on FR 2423.

Related Item

First Revision No. 2423-NFPA 70-2015 [New Definition after Definition: Vending Machine.]
Public Comment No. 485-NFPA 70-2015 [Section No. 404.22]

404.22   Electronic Lighting Control Switches.
Electronic lighting control switches shall be listed and labeled. They shall not introduce current on the equipment grounding conductor during normal operation. The requirement to not introduce current on the equipment grounding conductor shall take effect on January 1, 2020.

Exception: For dwelling unit installations existing prior to the effective date of 404.2(C), where the grounded conductor has not been provided in the switchbox and where installing the grounded conductor would require removing finish materials, electronic lighting control switches that introduce current on the equipment grounding conductor (as part of their normal operation) shall be permitted. These electronic lighting control switches shall be listed for the purpose and marked either on the device or smallest unit container with the following: "For use where the grounded (neutral) conductor is not provided in the outlet box" or equivalent.

Statement of Problem and Substantiation for Public Comment

UL does not support First Revision No. 2423.

Prior to the 2011 edition of the National Electrical Code, a grounded (neutral) conductor was not required at the switch location intended to control lighting loads. Without a neutral connection, many electronic control switches such as occupancy sensors must pass current through the grounding conductor to operate. Safety standards limit this current to 0.5 ma maximum.

UL supports the theory that electronic lighting control devices should not intentionally introduce current on the equipment grounding conductor during normal operation. This is especially true in installations where a grounded conductor has been installed in the device box. But prohibiting the ability to conduct a small amount of current (no more than 0.5ma) through the grounding conductor when the grounded conductor is not present, will eliminate a valuable, energy efficient, and safe product from the marketplace.

UL urges the panel to re-consider and introduce a practical solution whereby the Code permits this continued practice in a dwelling unit, where the installation predates the required grounded conductor at switch locations and where the addition of a grounded conductor would involve removing finish materials (refer to 404.2(C)(2) for precedence). Although this current is limited to 0.5ma, the limitation to a dwelling unit would further address any concern with the effect of cumulative current (0.5 mA maximum per device) on the grounding conductor because the number of switching devices likely to be present in dwelling unit applications is typically less than those installed in industrial or commercial applications.
