A licensed engineer seals documents that they have produced, or were produced under their supervision, with their state P.E. seal and signature. This is the only legal way of indicating approval or certification by a licensed engineer.

Submittal Date: Sat Sep 12 17:02:20 EDT 2015

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-976-NFPA 70-2015
Statement: Definition of "Engineering Supervision" has been deleted and actions required of the engineer supervising certain aspects of design have been included in the appropriate sections of the code. This is consistent with other uses of the term "engineering supervision" as used throughout the code.

**Public Comment No. 713-NFPA 70-2015 [ Definition: Engineering Supervision. ]**

**Engineering Supervision.**
Designed and approved (or certified) by a licensed professional engineer competent in the specific area under supervision.

**Statement of Problem and Substantiation for Public Comment**

This definition should be removed; as stated in Article 90.1 Purpose "This code is not intended as a design specification or an instruction manual for untrained persons." The code doesn't define designed, certified and competent engineer, one could argue that a civil engineer is competent in the specific area of fault current studies or relay settings for a substation. Additionally, The term approved is already defined in Article 100

Submitter Information Verification

Submitter Full Name: MARVIN HAMON
Organization: HAMON ENGINEERING INC
Street Address: City: State: Zip: Submittal Date: Sat Sep 12 17:43:29 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The new term does not match the past tense of the definition. CMP4 691 Task group corrected the term to “labeled” so this change is no longer needed.
Public Comment No. 715-NFPA 70-2015 [ Definition: Field Labeled (as applied to evaluated products... ]

Field Labeled (as applied to evaluated products).

Equipment or materials to which has been attached a label, symbol, or other identifying mark of an field evaluation body (FEB) indicating the equipment or materials were evaluated and found to comply with requirements as described in an accompanying field evaluation report. [790, 2012]

Statement of Problem and Substantiation for Public Comment

This section should be removed. Field evaluations (FE) are not defined in the NEC and are subject to interpretation by both NRTL’s and non-NRTL’s (private test labs). At what level of review is the FE process? Is testing required? Is document review only required? How or who qualifies the certification body performing the evaluation? What are the certification requirements of the test lab? Is the evaluator a licensed architect or civil engineer?

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-979-NFPA 70-2015
Statement: The definitions of a Utility Distribution System and Utility Transmission System have been deleted since they have been removed from the scope.
Definitions (691.2): Utility Dis... to Utility Tra...

Utility Distribution System.
An electrical system operated by a regulated utility company operating at an ac voltage greater than 1000 volts and less than 100,000 volts.

Utility Transmission System.
An electrical system operated by a regulated utility company operating at a voltage equal to or greater than 100,000 volts.

Statement of Problem and Substantiation for Public Comment

Unfortunately there is no standard in the industry that supports these voltage levels to identify distribution verses transmission systems. I have seen the break between distribution and transmission set at a number of voltages between 30kV and 120kV. Distribution covers everything down to the 240/120V conductors on the pole outside a residence.

The definition is also not needed since all PV systems interconnected to a utility interconnect at some point in the utility transmission or distribution system. Perhaps a better way of defining the interconnection would be to interconnect at voltages greater than 1000V?

Resolution: SR-979-NFPA 70-2015
Statement: The definitions of a Utility Distribution System and Utility Transmission System have been deleted since they have been removed from the scope.
691.4 Special Requirements for Large-Scale PV Electric Supply Stations.

Large-scale PV electric supply stations shall comply with the following:

1. Electrical circuits and equipment for large-scale PV electric supply stations are accessible only to qualified personnel needed for the maintenance and operation of the PV electric supply station. 

   Informational Note: Refer to NFPA 70E-2015, Standard for Electrical Safety in the Workplace, for electrical safety requirements.

2. Access to PV electric supply stations is restricted by fencing or other adequate means in accordance with 110.31. Field applied hazard markings shall be applied in accordance with 110.21(B).

3. The connection between the PV electric supply station and the utility transmission or distribution system is through medium- or high-voltage switch gear, substation, switch yard, or similar methods whose sole purpose is to safely and effectively interconnect the two systems.

4. The electrical loads within the supply station are only used to power auxiliary equipment for the generation of the PV power.

5. PV electric supply stations shall not be installed on buildings.

Statement of Problem and Substantiation for Public Comment

The reference to transmission and distribution removed from text. See comment on the definitions for Utility Transmission System and Utility Distribution System an comment on Scope.

Organization: HAMON ENGINEERING INC
Street Address: 
City: 
State: 
Zip: 
Submittal Date: Sat Sep 12 17:37:40 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-980-NFPA 70-2015
Statement: The SR adds language in the main paragraph to clarify that access to these sites is only available to authorized personnel. This can include guided tourists, inspectors, and qualified persons working on the station.

The panel modified language regarding the tasks of the qualified individuals.

The term "utility transmission and distribution system" is removed and the language modified to align with wording in 691.1. This eliminates the voltage sizing concerns but clarifies that the PV electric supply station is connected to a utility system that transfers electrical energy.

The term "large-scale" is added to the last item on the list to make it explicit that these systems are not installed on buildings.
Special Requirements for Large-Scale PV Electric Supply Stations.

Large-scale PV electric supply stations shall comply with the following:

1. Electrical circuits and equipment for large-scale PV electric supply stations are accessible only to qualified personnel needed for the maintenance and operation of the PV electric supply station. Informational Note: Refer to NFPA 70E-2015, Standard for Electrical Safety in the Workplace, for electrical safety requirements.

2. Access to PV electric supply stations is restricted by fencing or other adequate means in accordance with 110.31. Field applied hazard markings shall be applied in accordance with 110.21(B).

3. The connection between the PV electric supply station and the utility transmission or distribution system is through medium- or high-voltage switch gear, substation, switch yard, or similar methods whose sole purpose is to safely and effectively interconnect the two systems.

4. The electrical loads within the supply station are only used to power auxiliary equipment for the generation of the PV power.

5. PV electric supply stations shall not be installed on buildings.

Statement of Problem and Substantiation for Public Comment

I don't see any safety advantage to limiting access to something greater than qualified personnel only.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-980-NFPA 70-2015
Statement: The SR adds language in the main paragraph to clarify that access to these sites is only available to authorized personnel. This can include guided tourists, inspectors, and qualified persons working on the station.

The panel modified language regarding the tasks of the qualified individuals.

The term “utility transmission and distribution system” is removed and the language modified to align with wording in 691.1. This eliminates the voltage sizing concerns but clarifies that the PV electric supply station is connected to a utility system that transfers electrical energy.

The term “large-scale” is added to the last item on the list to make it explicit that these systems are not installed on buildings.
691.4 Special Requirements for Large-Scale PV Electric Supply Stations.

Large-scale PV electric supply stations shall comply with the following:

1. Electrical circuits and equipment for large-scale PV electric supply stations are accessible only to qualified personnel needed for the maintenance and operation of the PV electric supply station.

   Informational Note: Refer to NFPA 70E-2015, Standard for Electrical Safety in the Workplace, for electrical safety requirements.

2. Access to PV electric supply stations is restricted by fencing or other adequate means in accordance with 110.31. Field applied hazard markings shall be applied in accordance with 110.21(B). Add language to increase the height of the fence surrounding a substation on privately owned land to 8 ft. to be in line (consistent) with OSHA requirements.

3. The connection between the PV electric supply station and the utility transmission or distribution system is through medium- or high-voltage switch gear, substation, switch yard, or similar methods whose sole purpose is to safely and effectively interconnect the two systems.

4. The electrical loads within the supply station are only used to power auxiliary equipment for the generation of the PV power.

5. PV electric supply stations shall not be installed on buildings. I'm not sure why we were referencing this as other portions of the code would limit the installation; however if a company like BOEING wanted to install several 1MW arrays on let's say 6 buildings why would we limit this installation (6MW)?

Statement of Problem and Substantiation for Public Comment

OSHA 1926.403(J)(1) & (2) says for equipment operating at over 600V “a wall screen or fence less than 8 feet in height is not considered adequate to prevent access.”

Street Address:
City:
State:
Zip:
Submittal Date: Thu Sep 17 20:29:12 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: PC 718 recommends adding language to increase the height of the fence surrounding a substation on privately owned land to 8 ft. to be in line (consistent) with OSHA requirements, however this would be inconsistent with the NEC requirements in 110.31. Suggest the commenter make the proposal to 110.31. PC 718 further recommends allowing systems covered by 691 to be allowed on buildings. The CMP is limiting the scope of 691 to ground mounted systems to ensure that only qualified individual have access to the systems. Limiting access on roof mounted systems is not feasible as the roof serves multiple purposes other than supporting a PV system. Regardless of size, roof mounted systems will need to comply with 690 rather than 691.
Public Comment No. 719-NFPA 70-2015 [Section No. 691.5]

691.5 Equipment Approval.
All electrical equipment shall be approved for installation by one of the following:

1. Listing and labeling
2. Field labeling
3. Where products complying with 691.5(1) or (2) are not available, by engineering review validating that the electrical equipment is tested to relevant standards or industry practice. This section should be removed. The ability to have properly listed equipment is available even for all the 230kV components and below, through the use of IEEE Standards. STP’s need to be developed.

Statement of Problem and Substantiation for Public Comment
Field evaluations and engineering review are not defined in Article 100 NFPA 70. Part 2 and 3 should be removed.

Street Address:
City:
State:
Zip:
Submittal Date: Thu Sep 17 20:43:16 EDT 2015

Committee Statement
Committee Action: Rejected
Resolution: Field Labeled is defined in Article 100. The commenter recommends removing 691.5(3) and suggests the creation of Standards Technical Panels that can work on the listing of equipment for which there is currently no standard. The purpose of allowing equipment to be selected by a competent engineer is that there is not an existing method to list all equipment that used in large scale PV systems, therefore alternative methods must be used until standards exist.
691.6 Design Under Engineering Supervision.

Documentation of the engineered design of the electric supply station shall be provided upon request of the AHJ. An additional independent engineering report detailing compliance of the design with applicable standards and industry practice shall be provided upon request of the AHJ. The independent engineer shall be a licensed professional engineer competent in the specific area under review and selected in mutual agreement between the AHJ and engineer of record. This documentation shall include details of conformance of the design with Article 690, and any alternative methods to Article 690, or other articles of this Code.

Statement of Problem and Substantiation for Public Comment

This proposed change helps to ensure that the independent engineer has experience with large scale PV and that both parties are fairly represented. We would like to avoid scenarios in which the AHJ has complete control over the selection of the independent engineer as this would not seem to meet the intent of the independent engineering report referenced within 691.6.

State:
Zip:
Submittal Date: Fri Sep 25 14:12:59 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-982-NFPA 70-2015
Statement: The SR modifies the language to better reflect the actions that will be taken to confirm that the PV system was built in conformance to the design.

The language has also been revised to better articulate the process for choosing an independent engineer.
691.7 . Installation Under Engineering Supervision.

Documentation of the electric supply station installation shall be provided upon request of the AHJ. An additional independent engineering report detailing compliance with applicable standards and industry practice shall be provided upon request of the AHJ. This documentation shall include details of conformance of the installation with this Code, applicable standards, and industry practice. This documentation, where requested, shall be available prior to the commercial operation of the station.

Statement of Problem and Substantiation for Public Comment

This requirement for engineering supervision of installation will create a need for a service that a reasonable engineering company or engineer will not want to provide.

Engineers traditionally do not supervise construction projects or contractors and nowhere else in the NEC is it called out that an engineer will supervise a construction project. Engineers do provide construction observation which is performing site visits at appropriate intervals to inspect the work for general conformance with the design, but that is not an inspection or supervision.

Statement: The SR modifies the language to better reflect the actions that will be taken to confirm that the PV system was built in conformance to the design.

The language has also been revised to better articulate the process for choosing an independent engineer.
691.8 Direct Current Operating Voltage.

For large-scale PV electric supply stations operating at a dc voltage above 1000 volts, calculations shall be performed under engineering supervision. PV system dc conductors and equipment with a maximum voltage of 1500V or less do not need to comply with Article 490.

Statement of Problem and Substantiation for Public Comment

In PI#3181 it was proposed to raise the voltage limit in the scope of Art. 490 from 1000V to 2000V. The substantiation for PI#3181 pointed out that product standards for HV equipment begin at 2000V and that recent changes to product standards for low voltage equipment have raised requirements suitable for higher voltages up to 1500V or 2000V in some cases. In particular, for the PV industry there has been a lot of work done to revise product standards for switches, circuit breakers, fuses, modules, power conversion, etc. to cover PV system voltages up to at least 1500V. Such systems should not have to use the approaches in Art. 490, which are intended to address medium voltage installations at 2.4kV and higher using HV equipment. The burden such requirements place on PV systems are not justified at system voltages of 1500V or less using appropriately rated and approved equipment.

PI#3181 was resolved, but in their Resolution statement the CMP wrote "Increasing the upper limit may be practical in microenvironments such as those covered in Articles 690 or 694..." which indicates that it would be appropriate to narrow the scope of PI#3181 to just PV, and move it to Art. 690 and 691, which we are now doing with this Public Comment and a related one for a revision to 690.7.

Note that we would like to get both revisions accepted: this one to 691.8 and the related one for 690.7. However if the CMP feels that they cannot accept this 691.8 proposal, please consider the 690.7 proposal separately and on its own merit.

Submitter Full Name: JIM EICHNER
Organization: SCHNEIDER ELECTRIC
Street Address:
City:
State:
Zip:
Submittal Date: Wed Sep 23 16:06:35 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-983-NFPA 70-2015
Statement: 691.6 allows design of large scale PV systems to be performed under engineering supervision and requires documentation to be provided to the AHJ to demonstrate compliance with Article 690 or any alternative methods to Article 690. Article 690 includes information about listed equipment, rated 1500Vdc or less not being required to comply with 490.

The distinction between <=1kV and >1kV systems has been removed and replaced with a reference to 691.6.
691.8 Direct Current Operating Voltage.
For large-scale PV electric supply stations operating at a dc voltage above 1000 volts, calculations shall be performed under engineering supervision.

Statement of Problem and Substantiation for Public Comment

We support this language in principle but propose to strike/delete it because we do not believe it adds substance and may actually cause confusion for the following reasons:

1) 691.6 already allows design of large scale PV systems to be performed under engineering supervision and requires documentation to be provided to the AHJ to demonstrate compliance with Article 690 or any alternative methods to Article 690. Calling out a small subset of a large scale PV system design (i.e. max dc operating voltage calculation) and requiring that to be calculated under engineering supervision appears to be redundant.

2) Stating that DC system voltages >1kV shall be calculated under engineering supervision creates a distinction between systems <=1kV and systems >1kV and implies these two scenarios might be treated differently. We believe the intent of Article 691 is to allow maximum DC operating voltages (less than or greater than 1kV) for large scale PV systems to be calculated under engineering supervision. Therefore the distinction between <=1kV and >1kV systems should be removed.

3) 690.7 allows DC operating voltages to exceed 1kV under certain conditions, yet does not require calculation under engineering supervision for those systems that exceed 1kV.

The distinction between <=1kV and >1kV systems has been removed and replaced with a reference to 691.6.
Statement of Problem and Substantiation for Public Comment

This should be removed as the calculations for all aspects of the system are no different from any electrical system to include the medium voltage (just larger numbers). Seems obvious that an engineer would be involved with the design lets keep the book (NEC) to one volume and save a tree.

Article 690 includes information about listed equipment, rated 1500Vdc or less not being required to comply with 490.

The distinction between <=1kV and >1kV systems has been removed and replaced with a reference to 691.6.
691.9 Disconnection of Photovoltaic Equipment.

Isolating devices shall be permitted to be more than 1.8 m (6 ft) from the equipment where written safety procedures and conditions of maintenance and supervision ensure that only qualified persons service the equipment.

Informational Note: For information on lockout/tagout procedures, see NFPA 70E-2015, Standard for Electrical Safety in the Workplace.

Buildings whose sole purpose is to house and protect supply station equipment shall not be required to comply with 690.12.

Written standard operating procedures shall be available at the site detailing necessary shutdown procedures in the event of an emergency.

*Written safety procedures should be replaced with a sign/plaque/directory; personal experience, no one reads the written procedures. With that said again this is more in line with a document used by O & M and presented to the owner. (Are isolating devices defined in the NEC? Are they to be listed? If so, to what standard?)*

Statement of Problem and Substantiation for Public Comment

Written safety procedures should be replaced with a sign/plaque/directory; personal experience, no one reads the written procedures. With that said again this is more in line with a document used by O & M and presented to the owner. (Are isolating devices defined in the NEC? Are they to be listed? If so, to what standard?)

It seems we are adding language with no direction and/or definition of the components we are referring to. Suggest this section be removed, very vague as to component requirements and safe operating procedures for the disconnecting means and its design and certification requirements.

Committee Statement

Committee Action: Rejected
Resolution: In large-scale PV electric supply stations, the AC disconnect is located at the switchgear, which can be up to a mile away from the dozens of inverters at the site. Due to the large number of inverters in a large scale PV supply station, it is not possible to have all inverters in sight of the switchgear and their associated disconnects. The existing language does not prohibit plaques or directories from being provided.
Public Comment No. 728-NFPA 70-2015 [Section No. 691.10]

691.10 Arc-Fault Mitigation.

PV systems that do not comply with the requirements of 690.11 shall be designed under engineering supervision that includes fire mitigation plans to address dc arc-faults.

Remove in its entirety as most large solar installations have an O & M Building which may or may not have PV on the roof and would be required to meet this requirement; these buildings are occupied structures covered under the Building Code and contain sleeping quarters.

Statement of Problem and Substantiation for Public Comment

Remove in its entirety as most large solar installations have an O & M Building which may or may not have PV on the roof and would be required to meet this requirement; these buildings are occupied structures covered under the Building Code and contain sleeping quarters.

Committee Statement

Committee Action: Rejected  
Resolution: The scope of 691 is limited to ground mounted PV. If, within a Large Scale PV Generating Station, there were a building, such as an O&M building, which was designed for continuous human occupancy, all requirements of 690 would apply to the PV system installed on that building.
691.11 Fence Grounding.
Fence grounding requirements and details shall be provided under engineering supervision.

Statement of Problem and Substantiation for Public Comment

We support this language in principle but propose to strike/delete it because we do not believe it adds substance and may actually cause confusion for the following reasons:

1) 691.6 already allows design of large scale PV systems to be performed under engineering supervision and requires documentation to be provided to the AHJ to demonstrate compliance with Article 690 or any alternative methods to Article 690. Calling out a small subset of a large scale PV system design (i.e. fence grounding) and requiring the details to be provided under engineering supervision appears to be redundant.

2) Stating that fence grounding details must be provided under engineering supervision creates a distinction between fence grounding and other system grounding and implies these two aspects of large scale PV system grounding might be treated differently. We believe the intent of Article 691 is to allow large scale PV system grounding to be designed under engineering supervision. Therefore the distinction between fence grounding and all other large scale PV system grounding should be removed.

**Public Comment No. 729-NFPA 70-2015 [ Section No. 691.11 ]**

691.11 Fence Grounding.

Fence grounding requirements and details shall be provided under engineering supervision.

*Limit fence grounding to only areas where conductors travel over or under a fence and use approved isolators to limit migration of fault current in the construction of the build of the fence*

**Statement of Problem and Substantiation for Public Comment**

Limit fence grounding to only areas where conductors travel over or under a fence and use approved isolators to limit migration of fault current in the construction of the build of the fence.

The danger is where the feeder conductors operating at over 600v to ground travel over or under fenced in areas. These areas should also be designed with isolators within a specified distance of the conductors. Lets not require the entire fence to be grounded which could be several square miles of fencing.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

Public Comment No. 1066-NFPA 70-2015 [Section No. 694.1]

694.1 Scope.

This article applies to wind (turbine) electric systems that consist of one or more wind electric generators and their related alternators, inverters, controllers, and associated equipment.

Informational Note: Some wind electric systems are interactive with other electric power sources and some are standalone systems. Some systems have ac output and some have dc output. Some systems contain electrical energy storage, such as batteries.

Figure 694.1(a) Identification of Wind Electric System Components — Interactive System.

Figure 694.1(b) Identification of Wind Electric System Components — Stand-Alone System.

Statement of Problem and Substantiation for Public Comment

The general term "generator" encompasses both the DC generator and the AC alternator. Either of these can be used in a wind system. The way the text is written it limits wind generators to AC alternators.

Figure 694.1(a) uses "Outlet" for the output of the inverter and they could be misinterpreted to mean that an electrical outlet is used. Art. 690 uses "Electric Power Production and Distribution Network" for this call out. The figure is too specific by showing only an alternator based system and there are other types of systems.

Figure 694.1(b) is too specific, it shows an AC coupled alternator based system and there are DC generator based systems and AC coupled systems.

Public Comment No. 808-NFPA 70-2015 [Definition: Guy.]

Guy (as related to wind electrical systems).
A cable that mechanically supports a wind turbine tower.

Statement of Problem and Substantiation for Public Comment

All NFPA definitions are incorporated without change or comment into the NFPA Glossary of terms which simply indicates the code or standard where the definition originates. The definition of guy in the NEC can refer to multiple occupations or products and is not unique to article 694. If the panel wants to identify it in a different way, that would still comply with the concept that "guy" is too generic a term to stay as a definition that applies solely to a wind turbine cable. I can imagine multiple other concepts to which the term "guy" applies.

Committee Statement

Committee Action: Accepted
Resolution: SR-924-NFPA 70-2015
Statement: The definition only pertains to wind electric systems.
Public Comment No. 1371-NFPA 70-2015 [Section No. 694.7(B)]

(B) Equipment.

Wind electric systems shall be listed and or field labeled for the application. Wind electric systems under development or undergoing evaluation and testing for type certification and/or listing shall be permitted to be operated under conditions of engineering supervision in a controlled location with access limited to qualified personnel.

Statement of Problem and Substantiation for Public Comment

Field labeling is a common activity for large wind turbines, as they are often build as a batch using common components, but with some variation from batch to batch. It is impractical to type test or fully fix the design of large-scale wind turbines (this applies to listing of the overall assembly. In general, components are certified for the application). Field-labeling is sometimes also used for intermediate and small wind turbines, but they are more generally type-tested and listed. Questions regarding appropriate wording for listing and labeling were raised across the board for all articles in this code cycle. Wind turbines are a special case where either listing OR field labeling is appropriate.

The additional sentence regarding turbines under development is also important as a wind turbine cannot be listed or certified without several months of operating at a wide range of wind speeds. This certification testing is performed under engineering supervision in an access-limited environment (for example at the National Wind Test Center in Boulder, CO). Provision for such testing is necessary as the turbines still need to feed the power grid during this time, and so are subject to inspection and the NEC. Utility Interactive inverters are required to be NRTL listed to applicable ANSI standards and interconnection must comply with Article 705.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacturer remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

Committee Statement

Committee Action: Rejected
Resolution: The requirements of 694.18 in the 2014 NEC were moved in the first draft to Article 705. CMP4 then moved them to a new Article 710 (Stand-Alone Systems) in the second draft. The new Article makes this CC request unnecessary.
Public Comment No. 1405-NFPA 70-2015 [Section No. 694.15(C)]

(C) Direct-Current Rating.
Overcurrent devices, either fuses or circuit breakers, used in any dc portion of a wind electric system shall be listed and labeled for use in dc circuits and shall have appropriate voltage, current, and interrupting ratings.

| Statement: | The addition of the words “and labeled” provides information to the AHJ regarding the suitability of equipment they encounter. |
(B) Connection Through Disconnecting Means and Overcurrent Device.

(1) Number of Disconnecting Means.

(a) General. A single disconnecting means and associated overcurrent protective device(s) shall be permitted to be installed between the fire pump power source(s) and one of the following: [20:9.1.2]

1. A listed fire pump controller
2. A listed fire pump power transfer switch
3. A listed combination fire pump controller and power transfer switch

(b) Feeder Sources. For systems installed under the provisions of 695.3(C) only, additional disconnecting means and the associated overcurrent protective device(s) shall be permitted.

(c) On-Site Standby Generator. Where an on-site standby generator is used to supply a fire pump, an additional disconnecting means and an associated overcurrent protective device(s) shall be permitted.

(2) Overcurrent Device Selection.

Overcurrent devices shall comply with 695.4(B)(2)(a) or (b).

(a) Individual Sources. Overcurrent protection for individual sources shall comply with 695.4(B)(2)(a)(1) or (2).

1. Overcurrent protective device(s) shall be rated to carry indefinitely the sum of the locked-rotor current of the largest fire pump motor and the pressure maintenance pump motor(s) and the full-load current of all of the other pump motors and associated fire pump accessory equipment when connected to this power supply. Where the locked-rotor current value does not correspond to a standard overcurrent device size, the next standard overcurrent device size shall be used in accordance with 240.6. The requirement to carry the locked-rotor currents indefinitely shall not apply to conductors or devices other than overcurrent devices in the fire pump motor circuit(s). The requirement to carry the locked rotor currents indefinitely shall not apply to feeder overcurrent protective devices installed in accordance with 695.3(C). [20:9.2.3.4]

(2) Overcurrent protection shall be provided by an assembly listed for fire pump service and complying with the following:

a. The overcurrent protective device shall not open within 2 minutes at 600 percent of the full-load current of the fire pump motor(s).

b. The overcurrent protective device shall not open with a re-start transient of 24 times the full-load current of the fire pump motor(s).

c. The overcurrent protective device shall not open within 10 minutes at 300 percent of the full-load current of the fire pump motor(s).

d. The trip point for circuit breakers shall not be field adjustable. [20:9.2.3.4.1]

(b) On-Site Standby Generators. Overcurrent protective devices between an on-site standby generator and a fire pump controller shall be selected and sized to allow for instantaneous pickup of the full pump room load, but shall not be larger than the value selected to comply with 430.62 to provide short-circuit protection only. [20:9.6.1.1]
Disconnecting Means.

All disconnecting devices that are unique to the fire pump loads shall comply with items (a) through (e).

(a) **Features and Location — Normal Power Source.** The disconnecting means for the normal power source shall comply with all of the following:

1. Be identified as suitable for use as service equipment.
2. Be lockable in the closed position. The provision for locking or adding a lock to the disconnecting means shall be installed on or at the switch or circuit breaker used as the disconnecting means and shall remain in place with or without the lock installed.
3. Not be located within the same enclosure, panelboard, switchboard, switchgear, or motor control center, with or without common bus, that supplies loads other than the fire pump.
4. Be located sufficiently remote from other building or other fire pump source disconnecting means such that inadvertent operation at the same time would be unlikely.

   *Exception to 4: For a multibuilding campus-style complex(s) installed under the provisions of 695.3(C), only the requirements in 695.4(B)(3) (a)(2) shall apply for normal power source disconnects.*

(b) **Features and Location — On-Site Standby Generator.** The disconnecting means for an on-site standby generator(s) used as the alternate power source shall be installed in accordance with 700.10(B)(5) for emergency circuits and shall be lockable in the closed position. The provision for locking or adding a lock to the disconnecting means shall be installed on or at the switch or circuit breaker used as the disconnecting means and shall remain in place with or without the lock installed.

(c) **Disconnect Marking.** The disconnecting means shall be marked “Fire Pump Disconnecting Means.” The letters shall be at least 25 mm (1 in.) in height, and they shall be visible without opening enclosure doors or covers.

(d) **Controller Marking.** A placard shall be placed adjacent to the fire pump controller, stating the location of this disconnecting means and the location of the key (if the disconnecting means is locked).

(e) **Supervision.** The disconnecting means shall be supervised in the closed position by one of the following methods:

1. Central station, proprietary, or remote station signal device
2. Local signaling service that causes the sounding of an audible signal at a constantly attended point
3. Locking the disconnecting means in the closed position

(f) Sealing of disconnecting means and approved weekly recorded inspections when the disconnecting means are located within fenced enclosures or in buildings under the control of the owner

---

**Statement of Problem and Substantiation for Public Comment**

Resolution: SR-3622-NFPA 70-2015
Statement: This revision clarifies that the exception applies to all of 695.4(B)(3)(a) and not just to 695.4(B)(3)(a)(4).
Feeders.

Fire pump supply conductors on the load side of the final disconnecting means and overcurrent device(s) permitted by 695.4(B), or conductors that connect directly to an on-site standby generator, shall comply with all of the following:

(a) **Independent Routing.** The conductors shall be kept entirely independent of all other wiring.

(b) **Associated Fire Pump Loads.** The conductors shall supply only loads that are directly associated with the fire pump system.

(c) **Protection from Potential Damage.** The conductors shall be protected from potential damage by fire, structural failure, or operational accident.

(d) **Inside of a Building.** Where routed through a building, the conductors shall be protected from fire for 2 hours, shall be installed using one of the following methods:

The cable or raceway is

1. Be encased in a minimum 50mm(in) of concrete.

2. Be a listed fire resistive cable system.

   **Informational Note 1:** Fire resistive cables are tested to ANSI/UL 2196, Tests for Fire Resistive Cables.

   **Informational Note 2:** The listing organization provides information for fire resistive cable systems on proper installation requirements to maintain the fire rating.

1. Be protected by a fire rated assembly listed to achieve a minimum fire rating of 2 hours and dedicated to the fire pump circuit(s).

2. Be a listed electrical circuit protective system.

   **Informational Note 1:** Electrical circuit protective systems could include, but not be limited to, thermal barriers or a protective shaft and are tested to UL 1724, Fire Tests for Electrical Circuit Protection Systems.

   **Exception to (A)(2)(d):** The supply conductors located in the electrical equipment room where they originate and in the fire pump room shall not be required to have the minimum 2-hour fire separation or fire resistance rating, unless otherwise required by 700.10(D) of this Code.

**Statement of Problem and Substantiation for Public Comment**

See attached document for correct mark ups.

The revisions that were accepted in 695.6(A)(2)(d) changed time-proven methods of providing fire and mechanical protection to fire pump supply conductors without any substantiation of a problem with the existing requirements.

- The addition of the words “protected from fire for 2 hours” to 695.6 (A)(2)(d) is ambiguous and unenforceable for the concrete encasement allowance in (1). It could be interpreted that any amount of concrete is sufficient or it could be interpreted that the concrete assembly has to be tested to prove that it has a 2 hour fire rating. The allowance for 2” of concrete encasement has been in this section of the Code for years and has been recognized as providing both mechanical and fire protection sufficient for this application. During
the 2014 code cycle, a similar change was proposed using an International Building Code table showing fire resistive ratings of various concrete thicknesses as substantiation. It was defeated during the NFPA Technical Meetings. One of those supporting the motion to reject the change and to allow the continued use of 2” of concrete was the past chairman of the ASCE SFP Committee on Structural Fire Protection who stated that the use of that table was a “complete and total misapplication”. This time there was no substantiation at all to remove the 2” requirement.

- The additional changes made to this section do not add clarity. One removes the option for 2 hour fire-rated assemblies, which should be retained, and one adds “a listed fire resistive cable system” which is not necessary. According to the UL On-Line Certification Directory Guide Information for fire resistive cables listed to UL 2196 (Category FHJR), they must be used as part of a classified Electrical Circuit Protective System (Category FHIT) so they are already included in existing (3) “be a listed electrical circuit protective system with a minimum 2-hour fire rating”.

Resolution: The permission to use 2 inches of concrete was deleted in the first revision stage and is added back in this revision. The absence of a dimension for the depth of concrete would cause serious confusion in practical applications.
Public Comment No. 211-NFPA 70-2015 [Section No. 695.6(G)]

(G) Ground-Fault Protection of Equipment.

Ground-fault protection of equipment shall not be permitted for fire pumps.

No ground fault interruption means shall be installed in any fire pump control or power circuit.

[20:9.1.8.1]

Statement of Problem and Substantiation for Public Comment

With the changes and clarifications in FR 3652 and 3653, specifically 695.4(B)(1)(b) The rewording of existing text 695.6(G) with extracted text from NFPA 20 makes it clear that there may be ground protection upstream, but is not permitted in the Fire Pump Power Circuit.

Submittal Date: Mon Jul 13 13:08:55 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-3624-NFPA 70-2015
Statement: This revision will clarify that ground-fault protection of equipment is not permitted for the fire pump power circuit.

This revision is limited to the fire pump power circuit as 695.6 is titled “Power Wiring”.

This change is necessary to clarify that multi building campus style distribution systems may include upstream ground fault protection.

See NFPA 20: 9.1.8.1 for the NFPA 20 requirement.
Public Comment No. 658-NFPA 70-2015 [Section No. 695.14(E)]

(E) Electric Fire Pump Control Wiring Methods.

All electric motor–driven fire pump control wiring shall be in rigid metal conduit, intermediate metal conduit, electrical metallic tubing (EMT), liquidtight flexible metal conduit, liquidtight flexible nonmetallic conduit, listed Type MC cable with an impervious covering, or Type MI cable.

Statement of Problem and Substantiation for Public Comment

There was an editorial mistake made to FR 3656 as EMT should have been included as an acceptable wiring method for fire pump controls. Under the committee statement for this FR they stated “Electrical Metallic Tubing (EMT) is acceptable as a fire pump control wiring method” EMT should be added under the list of acceptable wiring methods.

City:
State:
Zip:
Submittal Date: Tue Sep 15 11:57:36 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-3625-NFPA 70-2015
Statement: This revision correctly adds electrical metallic tubing in the list of approved wire methods based on actions taken in the First Draft stage.
(F) Generator Control Wiring Methods.

Control conductors installed between the fire pump power transfer switch and the standby generator supplying the fire pump during normal power loss shall be kept entirely independent of all other wiring. Breakage, disconnecting, or shorting of the wires, or loss of power to the remote start circuits control conductors shall cause immediate starting and continuous running of the generator and shall not prevent the starting of the generator(s) due to causes other than failure of these external control circuits.

Informational Note: See NFPA 20-2013, Standard for the Installation of Stationary Pumps for Fire Protection, Section 3.3.7.2, for more information on fault-tolerant external control circuits.

The control conductors shall be protected to resist potential damage by fire or structural failure. They shall be permitted to be routed through a building(s) using one of the following methods:

1. Be encased in a minimum 50 mm (2 in.) of concrete.
2. Be protected by a fire-rated assembly listed to achieve a minimum fire rating of 2 hours and dedicated to the fire pump circuits.
3. Be a listed electrical circuit protective system with a minimum 2-hour fire rating. The installation shall comply with any restrictions provided in the listing of the electrical circuit protective system used.

Informational Note: The listing organization provides information for electrical circuit protective systems on proper installation requirements to maintain the fire rating.

Statement of Problem and Substantiation for Public Comment

The generator control expects a normally open or normally closed dry contact for the remote start circuit, and uses the generator starting battery system for power. If the generator battery system power is lost, the generator cannot start.

The last part of the second sentence in paragraph 1 conflicts with the first part and is unnecessary. The first part says that the generator shall start and run under the stated conditions, and the second part says that it shall not prevent the starting of the generators due to other causes. If the generator is already running, it’s a moot point.

Submittal Date: Thu Sep 24 12:42:23 EDT 2015

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-3626-NFPA 70-2015
Statement: The revised text provides necessary clarity. A generator cannot start if the control conductors lose power due to failed batteries. A new last sentence is added to require visual and audible annunciation where a loss of power prevent the starting of the generator.
Luminaire, Directly Controlled.

An emergency lighting luminaire that operates on constant power, line voltage and has a control input for an integral dimming or switching function that is used to drive the luminaire to full brightness, a specified level upon loss of normal power.

Informational Note No. 1: See ANSI/UL924, Emergency Lighting and Power Equipment for information covering directly controlled luminaires.

Informational Note No. 2: Some examples of protocols used for control inputs are ANSI E1.11 - DMX512, IEC 62386 - DALI, ANSI C82.11 - Annex A (0-10V).

Statement of Problem and Substantiation for Public Comment

Emergency luminaires, whether standard or directly controlled, may not always be powered on in normal operation. Hence the change of constant power to line voltage.

The requirements for emergency illumination do not require luminaires in an emergency mode to be on at full bright, just to provide the required illumination as determined by building codes such as NFPA 101. (Reference 700.1 and the definition of Emergency Systems in 700.2). In addition, Section 700.23 - Dimmer and Relay Systems - only requires energization of branch circuits required to provide minimum emergency illumination. In some respects, Directly Controlled Luminaires are essentially 1-channel dimmers integral to the luminaire.

The addition of Informational Note 2 is to provide examples of a few of the control methods used for Directly Controlled Luminaires to aid in understanding of the concept.

Resolution: 90.1(B) clearly states that compliance with the NEC and proper maintenance will result in an installation essentially free from hazard. Conditions of maintenance and the need for maintenance are within the scope of the NEC.
Public Comment No. 347-NFPA 70-2015 [Section No. 700.3(C)]

(C) Maintenance.

Emergency. The authority having jurisdiction shall require periodic maintenance. Emergency system equipment shall be maintained in accordance with manufacturer instructions and industry standards.

Statement of Problem and Substantiation for Public Comment

Making this change puts the "teeth" back into the requirement as in previous editions to allow the AHJ to require the maintenance on battery systems needed to assure proper operation of the emergency system. This particular AHJ is probably not the electrical inspector assuring proper initial installation of the equipment. Rather this AHJ is another party (possibly a third enforcement party) as described in the NEC definition in Article 100 of Authority Having Jurisdiction (AHJ). Maintenance is a variable, somewhat subjective requirement, contained in several industry standards, and is subject to the environment, use, and condition of the equipment. Only the AHJ responsible for maintenance (not initial installation) can evaluate all of the parameters of the battery installation and set up the proper/required periodic or reliability centered maintenance tasks for a battery system used in an emergency system.

Submittal Date: Tue Aug 04 13:02:24 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The proposed new first sentence is not necessary as the Authority Having Jurisdiction is required to enforce all of the requirements in the NEC.
(E) . Temporary Source of Power for Maintenance or Repair of the Alternate Source of Power.

If the emergency system relies on a single alternate source of power, which must be disabled for maintenance or repair, the emergency system shall include permanent switching means to connect a temporary alternate source of power for the duration of the maintenance or repair. The switching means shall comply with the following:

(1) Connection of the temporary alternate source of power shall not require disabling of the emergency system's normal source of power or disconnection of the emergency system's alternate source of power, other than by the switching means.

(2) Any transfer of power shall be in accordance with 700.12. It shall be permissible to utilize manual switching.

(3) The connection point for the temporary alternate source shall be marked with the phase rotation and system bonding requirements.

(4) Mechanical or electrical interlocking shall prevent inadvertent interconnection of power sources.

(5) The switching means shall include an "emergency source disabled" contact for connection to a generator remote annunciator or another facility alarm data collection point.

It shall be permissible to utilize the switching means for connection of a load bank.

Exception: A permanent switching means to temporarily connect an alternate source of power for the duration of the maintenance or repair shall not be required where one of the following conditions exists:

(1) All processes that rely on the emergency system source are capable of being disabled during maintenance or repair of the emergency source of power.

(2) The building or structure is unoccupied and fire suppression systems are fully functional and do not require an alternate power source.

(3) Other temporary means can be substituted for the emergency system.

(4) A permanent alternate emergency source, such as, but not limited to, a second on-site standby generator or separate electric utility service connection, capable of supporting the emergency system, exists.

Statement of Problem and Substantiation for Public Comment

The proposed new Section 700.3 (F) requires a means to connect a temporary generator during maintenance or repair of the prime generator. The concept for a portable, temporary source of power for generator maintenance was removed from 700.4 (B) in an effort to place the "maintenance" requirement in Section 700.3 which is titled "Tests and Maintenance", however, the requirement for portable temporary alternate source was originally required only for generators that are also used for peak load shaving. The requirement was also expanded as to how to provide the permanent means, and is far too specific.

This new Section can properly be interpreted to require all emergency generator systems, with a single generator or generators in parallel, to include a permanent docking station for a temporary portable generator, as the exceptions are vague.

Exception 1: An Inspector can correctly conclude that there are no emergency (life safety) processes that are capable of being disabled. Exception 2: Who is going to enforce or verify that the building is actually unoccupied?? (It will be occupied by the mechanic performing the maintenance)

Exception 3: It is unclear what "other temporary means" are. What about other permanent means??

Exception 4: It is unclear if generators operating in parallel meet this exception.

During the First Revision meetings, this proposed first draft revision was sent to an Ad Hoc committee, of which one of the members was this submitter, for further study/editing. This submitter believes the requirement is unnecessary, as there as only anecdotal evidence of an actual issue in the field.

If the Panel feels it should be a requirement in the NEC, this submitter recommends a motion of "Reject but Hold" to allow further study by a committee comprised individuals with appropriate expertise.

In addition, the text deleted in 700.4 (B) should remain.

Committee Statement

Committee Action: Rejected

Resolution: Where maintenance or repair is performed on an emergency generator, a portable or temporary alternate source must be available. This requirement significantly improves safety. The prescriptive requirements in new 700.3(F) are extremely feasible and can consist of an additional circuit breaker or bus to attach an alternate source. The exceptions provide relief where needed. The parent text of first level subdivision 700.3(F) is modified to require a portable or temporary alternate source to be available whenever the emergency generator is out of service for maintenance or repair.
Public Comment No. 788-NFPA 70-2015 [Section No. 700.3(F)]

(E) . Temporary Source of Power for Maintenance or Repair of the Alternate Source of Power.

If the emergency system relies on a single alternate source of power, which must be disabled for maintenance or repair, the emergency system shall include permanent switching means to connect a temporary alternate source of power for the duration of the maintenance or repair. The switching means shall comply with the following:

(1) Connection of the temporary alternate source of power shall not require disabling of the emergency system’s normal source of power or disconnection of the emergency system’s alternate source of power, other than by the switching means.

(2) Any transfer of power shall be in accordance with 700.12. It shall be permissible to utilize manual switching.

(3) The connection point for the temporary alternate source shall be marked with the phase rotation and system bonding requirements.

(4) Mechanical or electrical interlocking shall prevent inadvertent interconnection of power sources.

(5) The switching means shall include an “emergency source disabled” contact for connection to a generator remote annunciator or another facility alarm data collection point.

It shall be permissible to utilize the switching means for connection of a load bank.

Exception: A permanent switching means to temporarily connect an alternate source of power for the duration of the maintenance or repair shall not be required where one of the following conditions exists:

(1) All processes that rely on the emergency system source are capable of being disabled during maintenance or repair of the emergency source of power.

(2) The building or structure is unoccupied and fire suppression systems are fully functional and do not require an alternate power source.

(3) Other temporary means can be substituted for the emergency system.

(4) A permanent alternate emergency source, such as but not limited to, a second on-site standby generator or separate electric utility service connection, capable of supporting the emergency system, exists.

Statement of Problem and Substantiation for Public Comment

IEC’s position is to delete 700.3(F) - (FR 3616)

The proposed impact of this change is far reaching and the submitter did not provide any substantiation that the code text is needed. There are numerous ways to provide back-up power to a building in order to work on and maintain generators rather than mandating a specific requirement. Even if the requirement is placed into the code this doesn’t mean that an Owner or an Owner’s representative will follow through and rent a temporary generator. Typically when a generator is maintained a service tech is right near the generator. Should power be needed immediately the generator technician can suspend preventative maintenance work and turn on the generator in a split second.

Public Comment No. 1417-NFPA 70-2015 [ New Section after 700.4 ]

**TITLE OF NEW CONTENT**
Type your content here ...

(C) Voltage Regulation. (New) If a voltage range is provided by the equipment manufacturer, feeder and branch circuit conductors shall be sized to provide voltage at the equipment within the range that is required by the manufacturer. In addition, feeder and branch-circuit conductors shall be sized so the voltage at the end of the feeder conductor is not lower than 97% of that at the service or source and for branch circuits, not lower than 95% of the voltage at the service or source at the furthest outlet. Calculations shall be based on circuit loading at 80 percent of the rating of the overcurrent device.

**Statement of Problem and Substantiation for Public Comment**

The public deserves to have equipment that will provide reasonable operation for both safety and comfort. Where manufacturers are now worldwide it is important for safe and proper operation that conductors be sized properly to provide voltage within a standard operating range. When determined by the manufacturer, most offshore manufacturers have very low standards.

Submittal Date: Fri Sep 25 10:40:32 EDT 2015

**Committee Statement**

Committee Action: Rejected
Resolution: The intent of the submitter is met in the present text of 110.3(B). Listed and labeled equipment must be installed in accordance with their listing, labeling and manufacturers instructions.
700.4 Capacity and Voltage.
(A) Capacity and Rating.
An emergency system shall have adequate capacity and rating for all loads to be operated simultaneously. The emergency system equipment shall be suitable for the maximum available fault current at its terminals.

(B) Selective Load Pickup, Load Shedding, and Peak Load Shaving.
The alternate power source shall be permitted to supply emergency, legally required standby, and optional standby system loads where the source has adequate capacity or where automatic selective load pickup and load shedding is provided as needed to ensure adequate power to (1) the emergency circuits, (2) the legally required standby circuits, and (3) the optional standby circuits, in that order of priority. The alternate power source shall be permitted to be used for peak load shaving, provided these conditions are met.

Peak load shaving operation shall be permitted for satisfying the test requirement of 700.3(B), provided all other conditions of 700.3 are met.

(C) Voltage Regulation.
If a voltage range is provided by the equipment manufacturer, feeder and branch circuit conductors shall be sized to provide voltage at the equipment within the range that is required by the manufacturer. In addition, feeder and branch-circuit conductors shall be sized so the voltage at the end of the feeder conductor is not lower than 97% of that at the service or source and for branch circuits, not lower than 95% of the voltage at the service or source at the furthest outlet. Calculations shall be based on circuit loading at 80 percent of the rating of the overcurrent device.

Statement of Problem and Substantiation for Public Comment
It is important for safe and proper operation that conductors be sized properly to provide voltage within the operating range as determined by the manufacturer. It is very common for feeder conductors for emergency equipment to be lengthy so it is important that the conductors be sized properly so the electrical systems will perform safely and provide the purpose for which it is intended.

Submittal Date: Wed Jul 29 13:56:21 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-3602-NFPA 70-2015 See the Second Revision on 700.3(F) to modify the parent text of first level subdivision 700.3(F) to require a portable or temporary alternate source to be available whenever the emergency generator is out of service for maintenance or repair.
Statement: The deletion of the last sentence in 700.4(B) in first revision 3617 inadvertently removed the requirement for portable or temporary alternate sources to be available whenever the emergency generator is out of service for maintenance or repair.

This requirement is now added into the parent text of first level subdivision 700.3(F) to require a portable or temporary alternate source to be available whenever the emergency generator is out of service for maintenance or repair.

The previous requirement was incorrectly located in 700.4(B) Capacity, which limited application to standby generators used in emergency systems that were also used for selective load pickup, load shedding, and peak load shaving. The committee expands the requirement to all emergency generators where “maintenance or repair” is to be performed. Where an emergency system is required, provisions for supplementing the emergency standby generator during maintenance or repair are necessary.

Editorial revisions are made throughout the requirement to increase clarity and usability.
Public Comment No. 1416-NFPA 70-2015 [Section No. 700.5(C)]

(C) Automatic Transfer Switches.
Automatic transfer switches shall be electrically operated and mechanically held. Automatic transfer switches shall be listed, labeled and identified for emergency system use.

Statement of Problem and Substantiation for Public Comment

The term identified was added as UL 1008 requires that a transfer switch investigated for use in emergency systems or legally-required standby systems shall be marked “automatic transfer switch for emergency systems”.

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer's attestation that the product is in compliance with the appropriate standard. NRTL's conduct factory surveillance of products, surveillance is one method to validate the manufacturer's attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company's name, trade name, trademark or other authorized identification should be considered as being covered by UL's Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL's have similar requirements.

Public Comment No. 749-NFPA 70-2015 [Section No. 700.5(E)]

(E) Documentation.
The short-circuit current rating of the transfer equipment, based on the specific overcurrent protective device type and settings protecting the transfer equipment, shall be field marked on the exterior of the transfer equipment.

Statement of Problem and Substantiation for Public Comment

IEC's position is to delete 700.5 - (FR 7518)

The code already requires that equipment be installed according to available fault current, so adding this requirement is redundant. The installer/supplier already has the responsibility/liability to install the proper equipment based on the characteristics of the system. This proposal puts too much liability on the contractor/supplier because after installation various factors can change which will affect the available fault current. Feeders can be reworked, transformers can be changed with different impedance values, motor loads can be added to the existing system and similar factors that can change the available fault current. In the case of a lawsuit, the installer will have the burden of proof that the installation was done according to code and would result in unnecessary costs for defending an installation that was installed correctly, but that had variables change that are out of their control. A better proposal would be to require the owner to relabel the equipment after any alteration to the system.

Submittal Date: Fri Sep 18 20:35:53 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: Typically Automatic Transfer Switches have several overcurrent protection options each with different short-circuit current ratings (analogous to withstand close on ratings) which can cause confusion for AHJ during inspection or for service provider when replacing overcurrent protection after installation. This requirement requires the installer to mark the equipment exterior with the short-circuit current rating of the automatic transfer switch based upon the specific overcurrent protective device type/rating. This clarifies to the inspector and service provider the specifics of the protection scheme, which is vital for safety.
(A) Identification.

All boxes and enclosures (including transfer switches, generators, and power panels) for emergency circuits shall be permanently marked so they will be readily identified as a component of an emergency circuit or system. Where boxes or enclosures are not encountered the cable or raceway system shall be permanently marked to be identified as a component of the emergency system.

Receptacles supplied from the emergency system shall have a distinctive color or marking on the receptacle cover plates or the receptacles themselves.

Statement of Problem and Substantiation for Public Comment

The original input was rejected with the panel statement; that the intent of 700.10(A) was not to require all elements of the emergency be identified. The 2017 input was simply requesting when there were no boxes for identification that the raceway or cable system be identified in some manner. Requiring only boxes & enclosures to be identified misses the mark 50% of the time. It is common for metallic cable to daisy chain from emergency light to emergency light without installing a splice or junction box leaving the emergency system wiring method undistinguishable from the normal system. I can tell you that it is a difficult task for an inspector to try and follow a cable or raceway in a ceiling that is identical to every other cable or raceway in that same ceiling that is not distinguished. This requirement would benefit service electricians, inspectors and installers without any hardship. The method could be as simple as the spray painting the cable or conduit as installers do for grid wire identification. Please reconsider the rejection of the original input.

Submittal Date: Wed Sep 23 20:53:33 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-3603-NFPA 70-2015
Statement: The requirement for identifying emergency circuits is modified to address circuits that may not include junction boxes. The intent of 700.10(A) is to provide installers, maintainers and the AHJ with the ability to identify components of an emergency circuit or system. There are many circuits including but not limited to metal clad cable installations in lighting fixtures that use duplex connectors without junction boxes. These circuits are required to be identified. It is not intended that the entire length of raceways and cable assemblies be identified and a maximum distance between markings of 25 feet is added for clarity.
Public Comment No. 395-NFPA 70-2015 [Section No. 700.10(D) [Excluding any Sub-Sections]]

Emergency systems shall meet the additional requirements in (D)(1) through (D)(3) in assembly occupancies for not less than 1000 persons, or in buildings above 23 m (75 ft) in height, buildings classified as Use Group E with a total occupancy load of more than 300 occupants and buildings classified as Use Group I-2.

Statement of Problem and Substantiation for Public Comment

Fire protection of emergency systems should not be limited to high rise buildings or those buildings or portions of buildings with large occupancy loads. Schools (K-12) and Institutional occupancies housing people who are incapable of self-preservation should be included. Many schools and large hospitals are not high rise buildings or classed as Assembly occupancies, yet the importance and the challenges of safe evacuation in the event of fire are similar.

Panel 13 debated a proposal to include all building during the first draft meetings. The vote was a tie. Many were concerned with the financial impact on small business occupancies. This comment address the life safety importance of fire protection and the financial impact on some.

Committee Action: Rejected but see related SR
Resolution: SR-3612-NFPA 70-2015
Statement: Fire protection of emergency systems is necessary in many venues in addition to high-rise buildings and those buildings or portions of buildings with large occupancy loads. Schools (K-12) and Institutional venues housing people who are incapable of self-preservation must also be included. Many schools and large hospitals are not high-rise buildings or classed as assembly occupancies, yet should require emergency systems that are protected from fire for a minimum of 2-hours.
Public Comment No. 603-NFPA 70-2015 [Section No. 700.10(D)(1)]

(1) Feeder-Circuit Wiring. 

Feeder-circuit wiring shall be protected from fire for 2 hours using one of the following methods:

(1) The cable or raceway is installed in spaces or areas that are fully protected by an approved automatic fire suppression system.

(2) The cable or raceway is protected by a listed electrical circuit protective system with a minimum 2-hour fire rating.

   Informational Note No. 1: Electrical circuit protective systems could include but not be limited to thermal barriers, or a protective shaft and are tested to UL 1724, Fire Tests for Electrical Circuit Protection Systems.

   Informational Note No. 2: The listing organization provides information for electrical circuit protective systems on proper installation requirements to maintain the fire rating.

(3) Be a listed fire resistive cable system.

   Informational Note No. 1: Fire resistive cables are tested to ANSI/UL 2196, Tests for Fire Resistive Cables.

   Informational Note No. 2: The listing organization provides information for fire resistive cable systems on proper installation requirements to maintain the fire rating.

(4) The cable or raceway is encased in concrete 2 inches of concrete.

Statement of Problem and Substantiation for Public Comment

The draft indicates just "concrete encasement". This is very subjective and the potential risk of construction error is high. It has been shown in previous testing as noted in the 2008 NFPA Fire Protection Handbook Figure 19.2.2 that when a 6 inch slab of concrete is exposed for 2 hours in the ASTM E 119 fire test that the unexposed side of the slab at 2 inches will see a temperature of 357 C. The cable in the conduit is typically rated at 90 C so there would be a strong risk of circuit failure even at 2 inches. The more appropriate thickness would be in the area of 4 inches but that cannot be accommodated at this time of the draft. That means the 2 inch requirement at the very least should be kept in place.

Resolution: 
Statement: List item (4), for listed fire-rated assemblies with a minimum fire rating of 2 hours and contains only emergency circuits was deleted during the FR cycle and is added in this second revision. This means to achieve a 2-hour fire rating for emergency systems is time tested, and commonly used.

The permission to use 2-inches of concrete was also deleted in the first revision stage and is added back in this revision. The absence of a dimension for the depth of concrete would cause serious confusion in practical application.
Public Comment No. 786-NFPA 70-2015 [Section No. 700.10(D)(1)]

(1) Feeder-Circuit Wiring.
Feeder-circuit wiring shall be protected from fire for 2 hours using one of the following methods:

(1) The cable or raceway is installed in spaces or areas that are fully protected by an approved automatic fire suppression system

(2) The cable or raceway is protected by a listed electrical circuit protective system with a minimum 2-hour fire rating

   Informational Note No. 1: Electrical circuit protective systems could include but not be limited to thermal barriers, or a protective shaft and are tested to UL 1724, Fire Tests for Electrical Circuit Protection Systems.

   Informational Note No. 2: The listing organization provides information for electrical circuit protective systems on proper installation requirements to maintain the fire rating.

(3) Be a listed fire resistive cable system

   Informational Note No. 1: Fire resistive cables are tested to ANSI/UL 2196, Tests for Fire Resistive Cables.

   Informational Note No. 2: The listing organization provides information for fire resistive cable systems on proper installation requirements to maintain the fire rating.

(4) The cable or raceway is encased in a minimum of 50 mm (2 in.) of concrete

Statement of Problem and Substantiation for Public Comment

IEC's position is to leave the 2 inch concrete requirement in 700.10(D)(1) - (FR 3665)

IEC believes that substantiation has not been provided to eliminate the 2 inch concrete requirement when installing emergency feeders. Installing 2 inch of concrete around certain wiring methods has been in the NEC for numerous years with not one substantiated injury or death. Changing the text will reduce the overall clarity needed in the code.

Statement of Problem and Substantiation for Public Comment

The revisions that were accepted in 700.10(D)(1) through (5) change time-proven methods of providing fire and mechanical protection to these conductors without any substantiation of a problem with the existing requirements.

- The addition of the words “protected from fire for 2 hours” in 700.10(D)(1) is ambiguous and unenforceable for the concrete encasement allowance in new (4) which states: “the cable or raceway is encased in concrete”. It could be interpreted that any amount of concrete is sufficient or it could be interpreted that the concrete assembly has to be tested to prove that it has a 2-hour fire rating. The allowance for 2” of concrete encasement has been in this section of the Code for years and has been recognized as providing both mechanical and fire protection sufficient for this application. During the 2014 code cycle, a similar change was proposed using an International Building Code table showing fire resistive ratings of various concrete thicknesses as substantiation. It was defeated during the NFPA Technical Meetings. One of those supporting the motion to reject the change and to allow the continued use of 2” of concrete was the past chairman of the ASCE SFP Committee on Structural Fire Protection who stated that the use of that table was a “complete and total misapplication”. This time there was no substantiation at all to remove the 2” requirement.

- The additional changes made to this section do not add clarity. One removes the option for 2-hour fire-rated assemblies, which should be retained, and one adds “a listed fire resistive cable system” which is not necessary. According to the UL On-Line Certification Directory Guide Information for fire resistive cables listed to UL 2196 (Category FHRJ), they must be used as part of a classified Electrical Circuit Protective System (Category FHR) so they are already included in existing (2) “be a listed electrical circuit protective system with a minimum 2-hour fire rating”. We also question how an “approved automatic fire suppression system” is evaluated as meeting the requirement for 2-hour fire.
Committee Statement

Committee Action: Rejected but see related SR

Resolution: List item (4), for listed fire-rated assemblies with a minimum fire rating of 2 hours and contains only emergency circuits was deleted during the FR cycle and is added in this second revision. This means to achieve a 2-hour fire rating for emergency systems is time tested, and commonly used.

The permission to use 2-inches of concrete was also deleted in the first revision stage and is added back in this revision. The absence of a dimension for the depth of concrete would cause serious confusion in practical application.
Public Comment No. 1203-NFPA 70-2015 [Section No. 700.10(D)(3)]

**(3) Generator Control Wiring.**

Control conductors installed between the transfer equipment and the emergency generator shall be kept entirely independent of all other wiring and shall meet the conditions of 700.10(D)(1). Breakage, disconnecting, or shorting of the wires or loss of power to the remote start circuits control conductors shall cause immediate starting and continuous running of the generator and shall not prevent the starting of the generator(s) due to causes other than failure of these external control circuits.

**Statement of Problem and Substantiation for Public Comment**

The generator control expects a normally open or normally closed dry contact for the remote start circuit, and uses the generator starting battery system for power. If the generator battery system power is lost, the generator cannot start.

The last part of the second sentence conflicts with the first part and is unnecessary. The first part says that the generator shall start and run under the stated conditions, and the second part says that it shall not prevent the starting of the generators due to other causes. If the generator is already running, it's a moot point.

**Committee Statement**

**Committee Action:** Rejected but see related SR  
**Resolution:** SR-3611-NFPA 70-2015  
**Statement:** The revised text provides necessary clarity. A generator cannot start if the control conductors lose power due to failed batteries. A new last sentence is added to require visual and audible annunciation where a loss of power prevent the starting of the generator.
Current supply shall be such that, in the event of failure of the normal supply to, or within, the building or group of buildings
centered, emergency lighting, emergency power, or both shall be available within the time required for the application but not
to exceed 10 seconds. The supply system for emergency purposes, in addition to the normal services to the building and
meeting the general requirements of this section, shall be one or more of the types of systems described in 700.12(A) through
(E). Unit equipment in accordance with 700.12(F) shall satisfy the applicable requirements of this article.

In selecting an emergency source of power, consideration shall be given to the occupancy and the type of service to be
rendered, whether of minimum duration, as for evacuation of a theater, or longer duration, as for supplying emergency power
and lighting due to an indefinite period of current failure from trouble either inside or outside the building.

Equipment shall be designed and located so as to minimize the hazards that might cause complete failure due to flooding, fires,
icing, and vandalism.

Equipment for sources of power as described in 700.12(A) through (E) where located within assembly occupancies for greater
than 1000 persons or in buildings above 23 m (75 ft) in height with any of the following occupancy classes — assembly,
educational, residential, detention and correctional, business, and mercantile — shall be installed either in spaces fully
protected by approved automatic fire suppression systems (sprinklers, carbon dioxide systems, and so forth) or in spaces with a
1-hour fire rating shall comply with 700.10(D).

Informational Note No. 1: For the definition of Occupancy Classification, see Section 6.1 of NFPA 101-2015, Life
Safety Code. Informational Note No. 2: For further information, see ANSI/IEEE 493-2007, Recommended Practice for
the Design of Reliable Industrial and Commercial Power Systems.

Statement of Problem and Substantiation for Public Comment

This PI does not modify the number of occupants or height of the building.

All this does is coordinate this requirement with those located in section 700.10(D). Actually, 700.12 is in conflict with section 700.10(D)
as both 700.10(D) and 700.12 apply to assembly occupancies of not less than 1000 persons or in buildings above 23 m (75 ft) in height
and if not fully protected by an approved automatic fire suppression system, section 700.10(D) will require a 2 hour fire rated protection
system for the wiring or it has to be encased in a minimum of 50 mm (2 in.) of concrete.

However, as currently written, 700.12 will permit assembly occupancies with the same building height and occupant count if not fully
protected by an approved automatic fire suppression system to only have 1 hour fire rated protection.

This is confusing, does one need to comply with the two hour fire protection requirements of 700.10(D) or the one hour protection
requirements of 700.12?

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-3613-NFPA 70-2015
Statement: The action taken by the committee on the Second Revision to 700.10(D) to expand the fire protection requirements in
700.10(D) requires that correlation occur in section 700.12.

This revision adds “health care occupancies where persons are not capable of self preservation and educational
occupancies with more than 300 occupants” to correlate with the revisions in 700.10(D).
This revision does not represent new material. Public input 1246 sought the revisions seen in the FR to modify 700.10(D). In the first revision stage public input 1246 was resolved. If a first revision had occurred in 700.10(D) as suggested in public comment 1246, a first revision to correlate in 700.12 would have been necessary.
Public Comment No. 431-NFPA 70-2015 [Section No. 700.12(A)]

(A) Storage Battery.

Storage batteries shall be of suitable rating and capacity to supply and maintain the total load for a minimum period of 1 1/2 hours, without the voltage applied to the load falling below the load equipment manufacturer's minimum operating value 87-1/2 percent of normal. Automotive-type batteries shall not be used.

An automatic battery charging means shall be provided.

Statement of Problem and Substantiation for Public Comment

Eliminating the standardized 87.5% minimum battery retention threshold would be highly problematic for the listing of the equipment containing the storage batteries and for maintenance of the systems after installation. If the first revision is adopted as currently proposed, a marking will be required on every power source to identify (by manufacturer and model number) those loads for which it has been evaluated and found to provide the required 90 minutes of power. Additionally, field testing may be required when any of the connected emergency luminaires (the load equipment) need to be replaced, to verify that the power source has sufficient capacity. The minimum voltage requirement (in the 2014 and earlier editions) is what allows the power source and the load equipment to be independently certified and then mated in the field without the need for field testing for compatibility. The related product standard (UL 924) is benchmarked to this 87.5% threshold. This standardization should be restored and not be permitted to 'float' as suggested by the first revision. The flexibility gained does not adequately offset the unintended consequences for the majority of stakeholders.

Similar comments have been submitted in regards to the same issue under FR 3627, 3618, and 3628.

Committee Statement

Committee Action: Accepted
Resolution: SR-3606-NFPA 70-2015
Statement: The 87.5% minimum battery retention threshold is reinstated. The minimum voltage requirement allows the power source and the load equipment to be independently certified and then mated in the field without the need for field testing for compatibility. The related product standard (UL 924) is benchmarked to this 87.5% threshold.
Public Comment No. 433-NFPA 70-2015 [ Section No. 700.12(F)(2) ]

(2) Installation of Unit Equipment.
Unit equipment shall be installed in accordance with 700.12(F)(2)(1) through (6).

(1) The batteries shall be of suitable rating and capacity to supply and maintain the total lamp load associated with the unit in accordance with (a) or (b).

(b) For a period of at least 1 1/2 hours without the voltage falling below the equipment manufacturer's minimum operating voltage value.

The unit equipment shall supply and maintain not less than 60 percent of the initial emergency illumination for a period of at least 1 1/2 hours. Unit equipment shall be listed.

Informational note: See ANSI/UL 924, Emergency Lighting and Power Equipment, for information covering unit equipment.

(3) Unit equipment shall be permanently fixed in place (i.e., not portable) and shall have all wiring to each unit installed in accordance with the requirements of any of the wiring methods in Chapter 3. Flexible cord-and-plug connection shall be permitted, provided that the cord does not exceed 900 mm (3 ft) in length.

(4) The branch circuit feeding the unit equipment shall be the same branch circuit as that serving the normal lighting in the area and connected ahead of any local switches.

Exception: In a separate and uninterrupted area supplied by a minimum of three normal lighting circuits that are not part of a multiwire branch circuit, a separate branch circuit for unit equipment shall be permitted if it originates from the same panelboard as that of the normal lighting circuits and is provided with a lock-on feature.

(5) The branch circuit that feeds unit equipment shall be clearly identified at the distribution panel.

(6) Emergency luminaires that obtain power from a unit equipment and are not part of the unit equipment shall be wired to the unit equipment as required by 700.10 and by one of the wiring methods of Chapter 3.

(7) Remote heads providing lighting for the exterior of an exit door shall be permitted to be supplied by the unit equipment serving the area immediately inside the exit door.

Statement of Problem and Substantiation for Public Comment

Because subsection 700.12(F)(2)(5) allows remote luminaires to obtain power from the unit equipment batteries, the nominal 87-1/2% battery output voltage threshold must be maintained for field-mating compatibility purposes; otherwise, an operational field test will be needed every time such a remote luminaire is added or replaced if that remote luminaire is not specifically identified as suitable for use with the unit equipment at the time the unit equipment is listed. See my similar comment submitted under FR-3615. Also see similar comment submitted for 701.12(G), under FR-3628.

The simplest and most useful revision here is just to require the unit equipment to be listed and include an informational note pointing to UL 924 which addresses these products and includes the requirements for retention of battery power, along with a minimum light output requirement, at the end of 90 minutes (or longer, if the equipment is rated for longer operation). The standard performs this testing inclusive of any remote loads for which the equipment is rated and marked.

If the CMP does not want to rely exclusively on the product safety standard, then the 87-1/2% battery voltage should be retained in 700.12(F)(2)(1). I have submitted a second (separate) comment showing this option.

Terraview created a slight formatting problem – this comment suggests revising only subclause (1) of 700.12(F)(2). The subsequent subclauses, including their numbering, are intended to be left intact.

<td>The 87.5% minimum battery retention threshold is reinstated. The minimum voltage requirement allows the power source and the load equipment to be independently certified and then mated in the field without the need for field testing for compatibility. The related product standard (UL 924) is benchmarked to this 87.5% threshold.</td>
</tr>
</tbody>
</table>
(2) Installation of Unit Equipment.
Unit equipment shall be installed in accordance with 700.12(F)(2)(1) through (6).

(1) The batteries shall be of suitable rating and capacity to supply and maintain the total lamp load associated with the unit in accordance with (a) or (b):

   (a) For a period of at least 1 1/2 hours without the voltage falling below the equipment manufacturer's minimum operating voltage value 87-1/2 percent of normal battery voltage.

   (a) The unit equipment shall supply and maintain not less than 60 percent of the initial emergency illumination for a period of at least 1 1/2 hours.

(2) Unit equipment shall be permanently fixed in place (i.e., not portable) and shall have all wiring to each unit installed in accordance with the requirements of any of the wiring methods in Chapter 3. Flexible cord-and-plug connection shall be permitted, provided that the cord does not exceed 900 mm (3 ft) in length.

(3) The branch circuit feeding the unit equipment shall be the same branch circuit as that serving the normal lighting in the area and connected ahead of any local switches.

   Exception: In a separate and uninterrupted area supplied by a minimum of three normal lighting circuits that are not part of a multiwire branch circuit, a separate branch circuit for unit equipment shall be permitted if it originates from the same panelboard as that of the normal lighting circuits and is provided with a lock-on feature.

(4) The branch circuit that feeds unit equipment shall be clearly identified at the distribution panel.

(5) Emergency luminaires that obtain power from a unit equipment and are not part of the unit equipment shall be wired to the unit equipment as required by 700.10 and by one of the wiring methods of Chapter 3.

(6) Remote heads providing lighting for the exterior of an exit door shall be permitted to be supplied by the unit equipment serving the area immediately inside the exit door.

Statement of Problem and Substantiation for Public Comment

Because subsection 700.12(F)(2)(5) allows remote luminaires to obtain power from the unit equipment batteries, the nominal 87-1/2% battery output voltage threshold must be maintained for field-mating compatibility purposes; otherwise, an operational field test will be needed every time such a remote luminaire is added or replaced if that remote luminaire is not specifically identified as suitable for use with the unit equipment at the time the unit equipment is listed. See my similar comment submitted under FR-3615. Also see similar comment submitted for 701.12(G), under FR-3628.

The simplest and most useful revision here is just to require the unit equipment to be listed and include an informational note pointing to UL 924 which addresses these products and includes the requirements for retention of battery power, along with a minimum light output requirement, at the end of 90 minutes (or longer, if the equipment is rated for longer operation). The standard performs this testing inclusive of any remote loads for which the equipment is rated and marked. I have submitted this option under a separate comment. This comment has been submitted in case the CMP does not want to rely exclusively on the product safety standard for this issue.

Terraview created some formatting problems -- subclause numbering (a) and (b) should remain under 700.12(F)(2)(1). Also, I have not submitted any changes to the exception under 700.12(F)(2)(3), but for some unknown reason it has become underlined in this submittal.

NATIONAL FIRE PROTECTION ASSOCIATION REPORT

http://submittals.nfpa.org/TerraViewWeb/ContentFetcher?commentPara...
700.32 Selective Coordination.

Emergency system(s) overcurrent devices shall be selectively coordinated with all supply-side overcurrent protective devices.

Selective coordination shall be selected by a licensed professional engineer or other qualified persons engaged primarily in the design, installation, or maintenance of electrical systems. The selection shall be documented and made available to those authorized to design, install, inspect, maintain, and operate the system.

Exception: Selective coordination shall not be required between two overcurrent devices located in series if no loads are connected in parallel with the downstream device.

Exception: Selective coordination shall not be required between a paralleling breaker in a multiple generator paralleling system and downstream feeder devices.

Statement of Problem and Substantiation for Public Comment

While the panel dealt with my concerns in Public Input 1530 regarding ground fault issues with parallel applications, they did not deal with the 3rd point in my substantiation related to selective coordination in a paralleling application.

When multiple generators are paralleled on a common bus it is not uncommon for feeder breakers to be larger than the generator paralleling breakers that are “upstream” from the feeders. Consequently, it is impossible for a designer to demonstrate any level of coordination in the system unless it is assumed that all generators always equally share fault current and are always on the bus when the fault occurs–neither of which can be demonstrated to be true.

This change provides a means to deal with this concern in a similar fashion to how the panel dealt with the ground fault issues in paralleling applications.

Committee Statement

Committee Action: Rejected
Resolution: The additional text is not necessary. For parallel generator applications, there are many design, control, overcurrent protective device technologies, and overcurrent protection setting options whereby selective coordination is achievable between feeder overcurrent protective devices and generator paralleling circuit breakers, even when one or more generators fail to supply power.
Public Comment No. 750-NFPA 70-2015 [Section No. 701.5(D)]

(D) Documentation.
The short-circuit current rating of the transfer equipment, based on the specific overcurrent protective device type and settings protecting the transfer equipment, shall be field marked on the exterior of the transfer equipment.

Statement of Problem and Substantiation for Public Comment

IEC's position is to delete 701.5(D) - (FR 7519)

The code already requires that equipment be installed according to available fault current, so adding this requirement is redundant. The installer/supplier already has the responsibility/liability to install the proper equipment based on the characteristics of the system. This proposal puts too much liability on the contractor/supplier because after installation various factors can change which will affect the available fault current. Feeders can be reworked, transformers can be changed with different impedance values, motor loads can be added to the existing system and similar factors that can change the available fault current. In the case of a lawsuit, the installer will have the burden of proof that the installation was done according to code and would result in unnecessary costs for defending an installation that was installed correctly, but that had variables change that are out of their control. A better proposal would be to require the owner to relabel the equipment after any alteration to the system.

Submittal Date: Fri Sep 18 20:39:26 EDT 2015

Committee Statement

Committee Action: Rejected

Resolution: Typically Automatic Transfer Switches have several overcurrent protection options each with different short-circuit current ratings (analogous to withstand close on ratings) which can cause confusion for AHJ during inspection or for service provider when replacing overcurrent protection after installation. This requirement requires the installer to mark the equipment exterior with the short-circuit current rating of the automatic transfer switch based upon the specific overcurrent protective device type/rating. This clarifies to the inspector and service provider the specifics of the protection scheme, which is vital for safety.
Public Comment No. 257-NFPA 70-2015 [Section No. 701.6(D)]

(D) Ground Fault.

To indicate a ground fault in solidly grounded wye, legally required standby systems of more than 150 volts to ground and circuit-protective devices rated 1000 amperes or more. The sensor for the ground-fault signal devices shall be located at, or ahead of, the main system disconnecting means for the legally required standby source, and the maximum setting of the signal devices shall be for a ground-fault current of 1200 amperes. Instructions on the course of action to be taken in event of indicated ground fault shall be located at or near the sensor location.

For systems with multiple emergency sources connected to a paralleling bus, the ground fault sensor shall be permitted at an alternate location.

Informational Note: For signals for generator sets, see NFPA 110-2013, Standard for Emergency and Standby Power Systems.

Statement of Problem and Substantiation for Public Comment

Section 700.6 was modified per FR3638 to allow for proper ground fault sensing in a multiple source application. Apparently the same intended change did not get into 701.6 as was intended. The text proposed is identical that that in 700.6 (D).

Submitter Information Verification

Submitter Full Name: GARY OLSON
Organization: KW RX LLC
Street Address:
City:
State:
Zip:
Submittal Date: Thu Jul 16 09:44:41 EDT 2015

Committee Statement

Committee Action: Accepted
Resolution: SR-3608-NFPA 70-2015
Statement: First level subdivision 701.6(D) is revised to correlate with the revision made in section 700.6.
(A) Storage Battery.

Storage batteries shall be of suitable rating and capacity to supply and maintain the total load for a minimum period of 1 \(\frac{1}{2}\) hours without the voltage applied to the load falling below the load equipment manufacturer's minimum operating value 87-1/2 percent of normal. Automotive-type batteries shall not be used.

An automatic battery charging means shall be provided.

Statement of Problem and Substantiation for Public Comment

Eliminating the standardized 87.5% minimum battery retention threshold would be highly problematic for the listing of the equipment containing the storage batteries and for maintenance of the systems after installation. If the first revision is adopted as currently proposed, a marking will be required on every power source to identify (by manufacturer and model number) those loads for which it has been evaluated and found to provide the required 90 minutes of power. Additionally, field testing may be required when any of the connected emergency luminaires (the load equipment) need to be replaced, to verify that the power source has sufficient capacity. The minimum voltage requirement (in the 2014 and earlier editions) is what allows the power source and the load equipment to be independently certified and then mated in the field without the need for field testing for compatibility. The related product standard (UL 924) is benchmarked to this 87.5% threshold. This standardization should be restored and not be permitted to 'float' as suggested by the first revision. The flexibility gained does not adequately offset the unintended consequences for the majority of stakeholders.

Similar comments have been submitted in regards to the same issue under FR 3615, 3618, and 3628.

Related Item

First Revision No. 3627-NFPA 70-2015 [Section No. 701.12(A)]

Submitter Information Verification

Submitter Full Name: MICHAEL SHULMAN
Organization: UL LLC

City:
State:
Zip:
Submittal Date: Mon Aug 24 15:09:08 EDT 2015

Committee Statement

Committee Action: Accepted
Resolution: SR-3609-NFPA 70-2015
Statement: The 87.5% minimum battery retention threshold is reinstated. The minimum voltage requirement allows the power source and the load equipment to be independently certified and then mated in the field without the need for field testing for compatibility. The related product standard (UL 924) is benchmarked to this 87.5% threshold.
(G) Unit Equipment.

Individual unit equipment for legally required standby illumination shall consist of the following:

1. A rechargeable battery
2. A battery charging means
3. Provisions for one or more lamps mounted on the equipment and shall be permitted to have terminals for remote lamps
4. A relaying device arranged to energize the lamps automatically upon failure of the supply to the unit equipment

The batteries shall be of suitable rating and capacity to supply and maintain the total lamp load associated with the unit for not less than (a) or (b):

- For a period of \( 1 \frac{1}{2} \) hours, without the voltage falling below the equipment manufacturer’s minimum operating voltage value
- The unit equipment shall supply and maintain not less than 60 percent of the initial emergency illumination for a period of at least \( 1 \frac{1}{2} \) hours

Unit equipment shall be listed.

Informational note: See ANSI/UL 924, Emergency Lighting and Power Equipment, for information covering unit equipment.

Unit equipment shall be permanently fixed in place (i.e., not portable) and shall have all wiring to each unit installed in accordance with the requirements of any of the wiring methods in Chapter 3. Flexible cord-and-plug connection shall be permitted, provided that the cord does not exceed 900 mm (3 ft) in length. The branch circuit feeding the unit equipment shall be the same branch circuit as that serving the normal lighting in the area and connected ahead of any local switches. Legally required standby luminaires that obtain power from a unit equipment and are not part of the unit equipment shall be wired to the unit equipment by one of the wiring methods of Chapter 3.

Exception: In a separate and uninterrupted area supplied by a minimum of three normal lighting circuits, a separate branch circuit for unit equipment shall be permitted if it originates from the same panelboard as that of the normal lighting circuits and is provided with a lock-on feature.

Statement of Problem and Substantiation for Public Comment

Because subsection 701.12(G)(3) allows remote luminaires to obtain power from the unit equipment batteries, the nominal 87-1/2% battery output voltage threshold must be maintained for field-mating compatibility purposes; otherwise, an operational field test will be needed every time such a remote luminaire is added or replaced if that remote luminaire is not specifically identified as suitable for use with the unit equipment at the time the unit equipment is listed. See my similar comment submitted under FR-3615. Also see similar comment submitted for 700.12(F)(2)(1), under FR-3618.

The simplest and most useful revision here is just to require the unit equipment to be listed and include an informational note pointing to UL 924 which addresses these products and includes the requirements for retention of battery power, along with a minimum light output requirement, at the end of 90 minutes (or longer, if the equipment is rated for longer operation). The standard performs this testing inclusive of any remote loads for which the equipment is rated and marked.

If the CMP does not want to rely exclusively on the product safety standard, then the 87-1/2% battery voltage should be retained in 700.12(G)(4). I have submitted a second (separate) comment showing this option.

Organization: KW RX LLC
Street Address:
City:
State:
Zip:
Submittal Date: Thu Jul 16 10:31:26 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The additional text is not necessary. For parallel generator applications, there are many design, control, overcurrent protective device technologies, and overcurrent protection setting options whereby selective coordination is achievable between feeder overcurrent protective devices and generator paralleling circuit breakers, even when one or more generators fail to supply power.
702.5 Transfer Equipment.

Transfer equipment shall be suitable for the intended use and designed and installed so as to prevent the inadvertent interconnection of normal and alternate sources of supply in any operation of the transfer equipment. Transfer equipment and electric power production systems installed to permit operation in parallel with the normal source shall meet the requirements of Article 705.

Transfer equipment, located on the load side of branch circuit protection, shall be permitted to contain supplemental overcurrent protection having an interrupting rating sufficient for the available fault current that the generator can deliver. The supplementary overcurrent protection devices shall be part of a listed transfer equipment.

Transfer equipment shall be required for all standby systems subject to the provisions of this article and for which an electric utility supply is either the normal or standby source.

Exception No. 1: Temporary connection of a portable generator without transfer equipment shall be permitted where conditions of maintenance and supervision ensure that only qualified persons service the installation and where the normal supply is physically isolated by a lockable disconnecting means or by disconnection of the normal supply conductors.

Exception No. 2: The installation of listed meter-mounted transfer switches that are under the exclusive control of the electric utility, as permitted in accordance with 90.2(B)(5)a. are not under the purview of the NEC. Listed meter-mounted transfer switches for use with portable generators shall be of the floating neutral type and connected with listed cords. A warning sign meeting the requirements of 702.7(C) shall be installed on meter-mounted transfer switches that are listed for use with portable generators.

Informational Note: See UL1008M, Outline Of Investigation For transfer Switch Equipment, Meter Mounted, for the requirements for listed and labeling meter-mounted transfer switches.

The short-circuit current rating of the transfer equipment, based on the specific overcurrent protective device type and settings protecting the transfer equipment, shall be field marked on the exterior of the transfer equipment.

Statement of Problem and Substantiation for Public Comment

The UL 1008M standard for meter-mounted transfer switches was recently amended by UL to allow for the connection of a permanently installed generator. The scope of this UL standard, in Section 1.3 clearly states that these types of devices be under the exclusive control of the serving utility, and are not under the purview of the NEC. Utility installation are not under the purview of the NEC, however if the device was installed by an electrical contractor, the installation would be under the purview of the NEC and the UL listing of the device would be violated. The proposed language would bring clarity that these types of devices are UL listed as utility equipment to be installed by the utility, and under the utilities exclusive control, and not as listed electrical equipment that can be installed by an electrical contractor.

UL 1008M TRANSFER SWITCH EQUIPMENT, METER MOUNTED

1 Scope

1.1 These requirements cover automatic and non-automatic (manual) transfer switch equipment, operating at 600 V ac less, and intended for installation in a utility meter base, in ordinary locations only.

1.2 These devices are intended for use in optional standby systems only, and are intended for cord connection of a portable generator to power a premise wiring system, where the neutral (grounded circuit conductor) of the generator is not bonded to ground or the generator frame. Bonding of the neutral (grounded circuit conductor) to ground will occur within the meter base. These devices are not intended for use in Emergency or Legally Required Standby Systems.

1.3 The installation of these devices is intended to be under the exclusive control of the serving utility, and these are not considered under the purview of the National Electrical Code, NFPA 70.

1.4 An automatic transfer switch as covered by these requirements is a device that automatically transfers a common load from a normal supply to an alternate supply in the event of failure of the normal supply, and automatically returns the load to the normal supply when the normal supply is restored. An automatic transfer switch may be provided with a logic control circuit that inhibits automatic operation of the device from either a normal to an alternate supply, or from an alternate to a normal supply when the switch reverts to automatic operation upon loss of power to the load.

1.5 A non-automatic transfer switch as covered by these requirements is a device, operated manually by a physical action, or electrically by a remote control, for transferring a common load between a normal and alternate supply.

1.6 A transfer switch may incorporate overcurrent protection for the main power circuits.

1.7 These requirements only cover transfer switches which are completely enclosed when installed in a meter base in conjunction with the electrical utility meter.
1.8 Transfer switches are rated in amperes and are considered to be acceptable for total system transfer, which includes control of motors, electric-heating loads, and transformer loads.

<td>The present requirements for transfer switches already cover such installations. The purview of the NEC per 90.2 sets the applicability of these requirements.</td>
</tr>
</tbody>
</table>
Public Comment No. 751-NFPA 70-2015 [Section No. 702.5]

702.5 Transfer Equipment.
Transfer equipment shall be suitable for the intended use and designed and installed so as to prevent the inadvertent interconnection of normal and alternate sources of supply in any operation of the transfer equipment. Transfer equipment and electric power production systems installed to permit operation in parallel with the normal source shall meet the requirements of Article 705.

Transfer equipment, located on the load side of branch circuit protection, shall be permitted to contain supplemental overcurrent protection having an interrupting rating sufficient for the available fault current that the generator can deliver. The supplementary overcurrent protection devices shall be part of a listed transfer equipment.

Transfer equipment shall be required for all standby systems subject to the provisions of this article and for which an electric utility supply is either the normal or standby source.

Exception: Temporary connection of a portable generator without transfer equipment shall be permitted where conditions of maintenance and supervision ensure that only qualified persons service the installation and where the normal supply is physically isolated by a lockable disconnecting means or by disconnection of the normal supply conductors.

The short-circuit current rating of the transfer equipment, based on the specific overcurrent protective device type and settings protecting the transfer equipment, shall be field marked on the exterior of the transfer equipment.

Statement of Problem and Substantiation for Public Comment
IEC's position is to delete the last sentence in 702.5 - (FR 7520)

The code already requires that equipment be installed according to available fault current, so adding this requirement is redundant. The installer/supplier already has the responsibility/liability to install the proper equipment based on the characteristics of the system. This proposal puts too much liability on the contractor/supplier because after installation various factors can change which will affect the available fault current. Feeders can be reworked, transformers can be changed with different impedance values, motor loads can be added to the existing system and similar factors that can change the available fault current. In the case of a lawsuit, the installer will have the burden of proof that the installation was done according to code and would result in unnecessary costs for defending an installation that was installed correctly, but that had variables change that are out of their control. A better proposal would be to require the owner to relabel the equipment after any alteration to the system.

</thead>
<tbody>
<tr>
<td>Resolution:</td>
<td>Typically Automatic Transfer Switches have several overcurrent protection options each with different short-circuit current ratings (analogous to withstand close on ratings) which can cause confusion for AHJ during inspection or for service provider when replacing overcurrent protection after installation. This requirement requires the installer to mark the equipment exterior with the short-circuit current rating of the automatic transfer switch based upon the specific overcurrent protective device type/rating. This clarifies to the inspector and service provider the specifics of the protection scheme, which is vital for safety.</td>
</tr>
</tbody>
</table>
702.6 Signals...

(D) Ground Fault. To indicate a ground fault in a solidly grounded wye, optional standby system of more than 150 volts to
ground and circuit-protective devices rated 1000 amperes or more. The sensor for the ground-fault signal devices shall be
located at, or ahead of the main disconnecting means for the optional standby source, and the maximum setting of the signal
devices shall be for a ground-fault current of 1200 amperes. Instructions on the course of action to be taken in event of
indicated ground fault shall be located at or near the sensor location.

For systems with multiple emergency sources connected to a paralleling bus, the ground fault sensor shall be permitted to be at
an alternate location.

Statement of Problem and Substantiation for Public Comment

If there is no text addressing ground fault design in optional standby systems, the requirements elsewhere in the code must be
followed. This potentially makes optional standby system generators have different design requirements from more critical systems,
and compromises the safety of the system by not requiring display of the ground fault condition in the most commonly used location for
generator sets.

The text is intended to make optional standby generators meet the same requirements as those for 700 and 701, except that they are
required to provide ground fault protection rather than simply indication.

As I understand the text in 700.26 and 701.26, a modification to add section 702.26 is not required because ground fault protection is
required for these applications.

Submittal Date: Thu Jul 16 09:19:38 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The requirement for ground fault indication, found in Articles 700 and 701 is required because ground fault tripping is not
required, as indicated in Sections 700.27 and 701.26. In Article 702, there is no relief to ground fault protection. Where
ground fault protection is required by other sections in the Code, it will be required in the appropriate locations in Optional
Standby Systems. Therefore, ground fault indication is not required, as it will be apparent that there's a ground fault when
a breaker trips and the affected load loses power.
Public Comment No. 664-NFPA 70-2015 [Section No. 702.7(C)]

(C) Power Inlet Portable Connection

Where a power inlet, cord and plug connection is used for a temporary connection to connect a portable generator, a warning sign shall be placed near the inlet connection that is attached to the building or structure to indicate the type of derived system that the system is capable of based on the wiring of the transfer equipment system installed. The sign shall display one of the following warnings:

WARNING:

FOR CONNECTION OF A SEPARATELY DERIVED (NEUTRAL BONDED NEUTRAL TO FRAME) SYSTEM ONLY

or

WARNING:

FOR CONNECTION OF A NONSEPARATELY DERIVED (FLOATING NEUTRAL BOND TO FRAME REMOVED) SYSTEM ONLY

Statement of Problem and Substantiation for Public Comment

The terms power inlet, flanged surface inlet (see 406.7(D) and cord and plug are used to describe this portable connection. The panel stated Power inlet is a general term used for a cord and plug connection, this is not the case, cord and plug is the general term used throughout the code and it covers a wide variety of connections including but not limited to pin and sleeve, receptacle, flange inlet, attachment plug and power inlet. If this is the case there would be no need to include the term cord and plug in section 702.12(B) and section 702.12 (B) also calls out a flanged inlet! we need consistency. the word temporary is misleading as shown in the PI 2810 photos. This connection should be located at the building location that is why I suggested the "on the building" language. the neutral bonded and floating language is half the story written is generator industry language, and clear understanding is needed. I have a companion PC on a informational note to address this issue. I realize the panel is tiring to coincide with the generator product in the field however I spoke to a few Generator manufacturers and they stated the term floating neutral does not mean there is no neutral to frame connection, to them it means no neutral to ground anywhere in the system. Section 702.11 deals with this subject and refers you to 250.30. If the panel wants to protect the homeowner having them ask the right question when buying the generator is important.: such as I need a generator with a neutral bonded to the frame.

Submittal Date: Tue Sep 15 14:21:12 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The proposed revision does not increase clarity or usability.
Portable Generators 15 kW or Less.

Where a portable generator, rated 15 kW or less, is installed using a flanged inlet or other cord- and plug-type connection, a disconnect is used to disconnect a feeder or branch circuit passing through or supplying the premise wiring of a building or structure, an additional disconnecting means shall not be required, where ungrounded conductors serve or pass through a flanged inlet, when the portable generator is installed with in sight of the building or structure.

Statement of Problem and Substantiation for Public Comment

Portable connection through a cord and plug connection is the general term. the way it is written no disconnect is required? you always need a disconnect in this case it is the cord and plug. the generator could be placed behind a shed or remote from the building the cord and plug use could also be at this location, leaving no disconnecting means at the building or with in sight as required with other section 702.12. the premise wiring language clarifies this installation only applies when the portable generators supply is attached to the premise wiring.

Public Comment No. 974-NFPA 70-2015 [ Section No. 702.12(C) ]

(C) Power Inlets Rated at 100 Amperes or Greater, for Portable Generators.

Equipment containing power inlets for the connection of a generator source shall be listed for the intended use. Systems with power inlets shall be equipped with an interlocked disconnecting means.

Exception No. 1: If the inlet device is rated as a disconnecting means

Exception No. 2: Supervised industrial installations where permanent space is identified for the portable generator located within line of sight of the power inlets. Industrial installations where condition of maintenance and supervision ensure that only qualified persons service the equipment, shall not be required to have interlocked disconnecting means nor inlets rated as disconnects.

Statement of Problem and Substantiation for Public Comment

Having qualified persons service the equipment provides a safer installation/operation than having permanent space for the portable generator and within line of sight. The comment as submitted is more in alignment with the standard industrial exemptions granted elsewhere in the Code.

Committee Statement

Committee Action: Rejected
Resolution: The requirement for a “permanent identified space…within sight of the power inlets” is the basis for this industrial exception.
### Public Comment No. 1213-NFPA 70-2015 [Section No. 705.1]

**705.1 Scope.**

This article covers installation of one or more electric power production sources operating either in parallel with a primary source(s) of electricity, as intentionally islanded, as stand-alone, or in any combination thereof.

Informational Note: Examples of the types of primary sources include a utility supply or an on-site electric power source(s).

### Statement of Problem and Substantiation for Public Comment

A gap exists in the current code for both stand-alone and intentionally islanded systems, both of which typically involve the interconnection of multiple power sources but which were not directly addressed under 705. By revising the scope of 705 to clarify it applies to systems operating in parallel, as stand-alone, intentionally islanded or any combination, this article can clearly address these systems. Additional requirements for stand-alone and intentionally islanded systems are currently under consideration through other actions in this code cycle, this proposal is intended to coordinate with them.

Statement: This new language provides clarity and incorporates the request of the CC to remove “and/or”. The informational note was added to clarify that 90.2(B)(5) excludes electric utilities.
Island Interconnection Device (IID).
A device that allows an intentionally islanded system to separate from and reconnect to a primary power source.

Statement of Problem and Substantiation for Public Comment

The interconnection function is already addressed in existing requirements and standards, and should not be duplicated in this manner. UL standards for interactive product address the specific considerations that must be addressed for this application and listed Interactive inverters which manage the interconnection to the area EPS are available from numerous manufacturers, yet these devices are not marked as being "Island Interconnection Devices" and so would not appear to comply with this requirement. In addition, there is no functional requirement for an intentionally islanded system to perform a seamless transfer, other than customer convenience; a listed manual double throw safety switch would provide the same level of safety, albeit at a lower level of convenience, but is not marked as an Island Interconnection Device. Overcurrent protection, disconnecting means, synchronizing means and the protection from multiple sources are addressed elsewhere in this article, so there is no benefit from adding this new requirement, only added complexity and potential confusion to AHJs and installers.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-989-NFPA 70-2015
Statement: This new language replaces the term “intentionally islanded” with the current industry term, “microgrid.”
**Island Interconnection Device (IID).**

A device that allows an microgrid (intentionally islanded) system to separate from and reconnect to a primary power source.

**Statement of Problem and Substantiation for Public Comment**

The term "intentionally islanded system" has been superseded in common usage and IEEE and IEC standards with the word "microgrid". IEEE in its new standard 2030.7 (Microgrid Controllers) has adopted the term Microgrid Interconnect Device, rather than Island Interconnect Device, as the former is self explanatory, while the latter is ambiguous. By 2017, the term "intentional island" will probably have disappeared entirely, as its source (IEEE 1547.4) is likely to be superseded.

Resolution: SR-992-NFPA 70-2015
Statement: The panel agrees these references are needed in this table. Stand Alone Systems Article 710 should show track change underline.
705.6 Equipment Approval.

All equipment shall be approved for the intended use. Utility-interactive inverters for interconnection systems are interactive, equipment intended to operate in parallel with the electric power system including, but not limited to, interactive inverters, engine generators, energy storage equipment, and wind turbines shall be listed and/or field labeled, and identified for the intended use of interconnection service.

Statement of Problem and Substantiation for Public Comment

This input is intended to clean up fragmented language and eliminate repetition, while maintaining the intent of the PI. Identification and options for field labeling is addressed in 110.3, and do not need to be repeated here. Inverters, wind turbines, energy storage systems and other equipment intended to operate in parallel with other sources are listed and marked as interactive, not as interconnection service. The incorrect language could lead to confusion with AHJs and installers.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacturer remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company's name, trade name, trademark or other authorized identification should be considered as being covered by UL's Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

Public Comment No. 1866-NFPA 70-2015 [Section No. 705.6]

705.6 Equipment Approval.
All equipment shall be approved for the intended use. Utility-interactive inverters for interconnection systems interactive equipment intended to operate in parallel with the electric power system including, but not limited to, interactive inverters, engine generators, energy storage equipment, and wind turbines shall be listed and or field labeled, and identified for the intended use of interconnection service.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs that further consideration be given to the comments expressed in voting on FR 1039. The Correlating Committee directs the panel to consider removing “Utility” from “Utility-interactive” as the first word of the second sentence to correlate with FR 955.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-994-NFPA 70-2015
Statement: This panel action corrects a grammar issue.
705.12  Point of Connection.

The output of an interconnected electric power source shall be connected as specified in 705.12(A) or (B), (C), or (D).

(A)  Supply Side.

An electric power production source shall be permitted to be connected to the supply side of the service disconnecting means as permitted in 230.82(6). The sum of the ratings of all overcurrent devices connected to power production sources shall not exceed the rating of the service.

(B)  Integrated Electrical Systems.

The outputs shall be permitted to be interconnected at a point or points elsewhere on the premises where the system qualifies as an integrated electrical system and incorporates protective equipment in accordance with all applicable sections of Article 685.

The outputs shall be permitted to be interconnected at a point or points elsewhere on the premises where all of the following conditions are met:

1. The aggregate of non-utility sources of electricity has a capacity in excess of 100 kW, or the service is above 1000 volts.

2. The conditions of maintenance and supervision ensure that qualified persons service and operate the system.

3. Safeguards, documented procedures, and protective equipment are established and maintained.

4. If the interconnection occurs in a switchboard or a panelboard that is fed simultaneously by a primary source(s) of electricity, and where this distribution equipment is capable of supplying multiple branch circuits or feeders or both, the interconnecting provisions for the interconnected electric power production source shall comply with 705.12(D)(1) through (D)(5).

(D)

Greater Than 100 kW.

Load Side.

The output of an electric power production source shall be permitted to be connected to the load side of the service disconnecting means of the other source(s) at any distribution equipment on the premises. Where distribution equipment, including switchgear, switchboards, or panelboards, is fed simultaneously by a primary source(s) of electricity and one or more other power source(s), and where this distribution equipment is capable of supplying multiple branch circuits or feeders, or both, the interconnecting provisions for other power sources shall comply with 705.12(D)(1) through (D)(5).

1. Dedicated Overcurrent and Disconnect.

Each source interconnection of one or more power sources installed in one system shall be made at a dedicated circuit breaker or fusible disconnecting means.
(2) Bus or Conductor Ampere Rating.

One hundred twenty-five percent of the power source output circuit current shall be used in ampacity calculations for the following:

(1) Feeders. Where the power source output connection is made to a feeder at a location other than the opposite end of the feeder from the primary source overcurrent device, that portion of the feeder on the load side of the power source output connection shall be protected by one of the following:

   (2) The feeder ampacity shall be not less than the sum of the primary source overcurrent device and 125 percent of the power source output circuit current.

   (3) An overcurrent device on the load side of the power source connection shall be rated not greater than the ampacity of the feeder.

(4) Taps. In systems where power source output connections are made at feeders, any taps shall be sized based on the sum of 125 percent of the power source(s) output circuit current and the rating of the overcurrent device protecting the feeder conductors as calculated in 240.21(B). Power source output circuit conductors, where smaller than the feeder conductors, shall be sized to carry not less than the larger of 705.60 or 240.21(B).

(5) Busbars. One of the methods that follows shall be used to determine the ratings of busbars in panelboards.

   (a) The sum of 125 percent of the power source(s) output circuit current and the rating of the overcurrent device protecting the busbar shall not exceed the ampacity of the busbar.

      Informational Note: This general rule assumes no limitation in the number of the loads or sources applied to busbars or their locations.

   (b) Where two sources, one a primary power source and the other another power source, are located at opposite ends of a busbar that contains loads, the sum of 125 percent of the power source(s) output circuit current and the rating of the overcurrent device protecting the busbar shall not exceed 120 percent of the ampacity of the busbar. The busbar shall be sized for the loads connected in accordance with Article 220. A permanent warning label shall be applied to the distribution equipment adjacent to the back-fed breaker from the power source that displays the following or equivalent wording:

      WARNING:

      POWER SOURCE OUTPUT CONNECTION —

      DO NOT RELOCATE THIS OVERCURRENT DEVICE.

      The warning sign(s) or label(s) shall comply with 110.21(B).

   (c) The sum of the ampere ratings of all overcurrent devices on panelboards, both load and supply devices, excluding the rating of the overcurrent device protecting the busbar, shall not exceed the ampacity of the busbar. The rating of the overcurrent device protecting the busbar shall not exceed the rating of the busbar. Permanent warning labels shall be applied to distribution equipment displaying the following or equivalent wording:

      WARNING:

      THIS EQUIPMENT FED BY MULTIPLE SOURCES.

      TOTAL RATING OF ALL OVERCURRENT DEVICES

      EXCLUDING MAIN SUPPLY OVERCURRENT DEVICE

      SHALL NOT EXCEED AMPACITY OF BUSBAR.

      The warning sign(s) or label(s) shall comply with 110.21(B).

   (d) Connections shall be permitted on multiple-ampacity busbars or center-fed panelboards where designed under engineering supervision that includes fault studies and busbar load calculations.

(3) Marking.

Equipment containing overcurrent devices in circuits supplying power to a busbar or conductor supplied from multiple sources shall be marked to indicate the presence of all sources.

(4) Suitable for Backfeed.

Circuit breakers, if backfed, shall be suitable for such operation.

Informational Note: Fused disconnects, unless otherwise marked, are suitable for backfeeding.
Listed plug-in-type circuit breakers backfed from interactive inverters or other electric power sources that are listed and identified as interactive shall be permitted to omit the additional fastener normally required by 408.36(D) for such applications.

Statement of Problem and Substantiation for Public Comment

With the change of title of 705.12(D) to "Load Side" and the text change from "inverter" to "power source" 705.12(D) now applies to all types of energy source interconnections. Since 705.12(D) allows interconnection "at any distribution equipment on the premises" it negates the need for B or C which made special allowances for systems that could be interconnected at other points on the premises. Sections B and C now serve no purpose and can be removed. All systems simply are load side or supply side interconnected, significant simplifying 705.12.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-997-NFPA 70-2015
Statement: The first paragraph is revised to match the text in 705.12.

The last sentence of the paragraph on Taps is deleted, and the concept moved to 705.60, which is more appropriate.

A new item (2)(3)(d) is added to permit connections to center-fed panels in dwellings at either end while maintaining the 120 percent rule.

(5) is revised for clarity.
(2) Bus or Conductor Ampere Rating.

One hundred twenty-five percent of the power source output circuit current shall be used in ampacity calculations for the following:

(1) Feeders. Where the power source output connection is made to a feeder at a location other than the opposite end of the feeder from the primary source overcurrent device, that portion of the feeder on the load side of the power source output connection shall be protected by one of the following:

(2) The feeder ampacity shall be not less than the sum of the primary source overcurrent device and 125 percent of the power source output circuit current.

(3) An overcurrent device on the load side of the power source connection shall be rated not greater than the ampacity of the feeder.

(4) Taps. In systems where power source output connections are made at feeders, any taps shall be sized based on the sum of 125 percent of the power source(s) output circuit current and the rating of the overcurrent device protecting the feeder conductors as calculated in 240.21(B). Power source output circuit conductors, where smaller than the feeder conductors, shall be sized to carry not less than the larger of 705.60 or 240.21(B).

(5) Busbars. One of the methods that follows shall be used to determine the ratings of busbars in panelboards.

(a) The sum of 125 percent of the power source(s) output circuit current and the rating of the overcurrent device protecting the busbar shall not exceed the ampacity of the busbar.

Informational Note: This general rule assumes no limitation in the number of the loads or sources applied to busbars or their locations.

(b) Where two sources, one a primary power source and the other another power source, are located at opposite ends of a busbar that contains loads, the sum of 125 percent of the power source(s) output circuit current and the rating of the overcurrent device protecting the busbar shall not exceed 120 percent of the ampacity of the busbar. The busbar shall be sized for the loads connected in accordance with Article 220. A permanent warning label shall be applied to the distribution equipment adjacent to the back-fed breaker from the power source that displays the following or equivalent wording:

WARNING:
POWER SOURCE OUTPUT CONNECTION —
DO NOT RELOCATE THIS OVERCURRENT DEVICE.

(c) The warning sign(s) or label(s) shall comply with 110.21(B).

(d) The sum of the ampere ratings of all overcurrent devices on panelboards, both load and supply devices, excluding the rating of the overcurrent device protecting the busbar, shall not exceed the ampacity of the busbar. The rating of the overcurrent device protecting the busbar shall not exceed the rating of the busbar. Permanent warning labels shall be applied to distribution equipment displaying the following or equivalent wording:

WARNING:
THIS EQUIPMENT FED BY MULTIPLE SOURCES,
TOTAL RATING OF ALL OVERCURRENT DEVICES
EXCLUDING MAIN SUPPLY OVERCURRENT DEVICE
SHALL NOT EXCEED AMPACITY OF BUSBAR.

The warning sign(s) or label(s) shall comply with 110.21(B).

(e) Connections shall be permitted on multiple-ampacity busbars or center-fed panelboards where designed under engineering supervision that includes available fault studies, current and busbar load calculations.

Statement of Problem and Substantiation for Public Comment

The following is an email from Fred Hartwell of CMP9 and who was involved with the original 2008 NEC approval of the 120% rule
related to panelboards.

****Hartwell email dated 3/29

I think there is a fundamental misunderstanding of the 100% rule versus the 120% rule that pervades some current NEC requirements in 705.12(D) as well as the Wiles articles, which I have now reread more carefully than I should have when they first came out.

First, the 120% rule has nothing to do with busbar overloading. I can take a panelboard bus and protect opposite ends at 100% of rating (thus, connect it to sources at 200% of its rating), and never subject it to more amperes than its ampacity would allow. For example, consider a 200A bus with 200A supply circuit breakers arranged at opposite ends. No segment of the intervening busbars will see over 200A of current. If we had 250A of load connected to this busbar, there are two possibilities: Either one end receives over 200A, or not. If over 200A comes in from one side, then that side trips and regular conditions apply from the other end. If less than 200A comes in from one side, then the remaining current comes in from the other side which subtracts from the current needed from the first side. The 200A number cannot be exceeded in practice.

Second, even though the busbars could not be overloaded in terms of ampacity, the panelboard as an entity can be overloaded in terms of power delivered with any multiple sources of supply totaling above 100% of the rating for which it was tested. In the above example, the 200A bus assembly delivers 400A times voltage times applicable power factor in the form of power. My understanding, and this goes back to that cell phone conversation with the former CMP 9 NEMA rep I elaborated on at length in one of our previous conversations, is that this power density provides an overall heating effect that the panelboard manufacturers have not designed for.

The 120% rule should be understood, therefore, as an allowable fudge factor that can be applied due to concerns about practicalities and the knowledge that there doesn’t seem to be any loss experience to challenge it. I am looking at language that allows the 120% rule to be extended to a center-fed panelboard even though the 100% protection rule has an academic potential of being violated in some minor way unlikely to be experienced in the real world.

******End of email.

This email explains that the removal of the requirement of the opposite end of the busbar will not have a significant impact on the thermal loading of a panelboard. To simplify the process for enforcement and construction, removal of the opposite end of the busbar will be simpler and essentially no different than applying the current rule for the opposite end of the busbar.

The last comment edits the wording of the last section about multi-ampacity buswork by removing the reference to center-fed panels, since it is now longer relevant. Also, it clarifies the original wording to specifically address the relevant concern of available fault current rather than the less defined term of fault studies.
Bus or Conductor Ampere Rating.

One hundred twenty-five percent of the power source output circuit current shall be used in ampacity calculations for the following:

1. **Feeders.** Where the power source output connection is made to a feeder at a location other than the opposite end of the feeder from the primary source overcurrent device, that portion of the feeder on the load side of the power source output connection shall be protected by one of the following:

   a. The feeder ampacity shall be not less than the sum of the primary source overcurrent device and 125 percent of the power source output circuit current.

   b. An overcurrent device on the load side of the power source connection shall be rated not greater than the ampacity of the feeder.

2. **Taps.** In systems where power source output connections are made at feeders, any taps, the output conductors shall be sized based on the sum of 125 percent of the power source(s) output circuit current and the permitted to be sized as tap conductors according to 240.21(B) under the following conditions:

   a. For calculation purposes, the assumed rating of the overcurrent device protecting the feeder conductors as calculated in 240.21(B). Power source output circuit conductors, where smaller than the feeder conductors, shall be sized to carry not less than the larger of 705.60 or 240.21(B).

   b. The power source output conductors and overcurrent device shall not be smaller than required by 705.60.

5. **Busbars.** One of the methods that follows shall be used to determine the ratings of busbars in panelboards.

   a. The sum of 125 percent of the power source(s) output circuit current and the rating of the overcurrent device protecting the busbar shall not exceed the ampacity of the busbar.

   Informational Note: This general rule assumes no limitation in the number of the loads or sources applied to busbars or their locations.

   b. Where two sources, one a primary power source and the other another power source, are located at opposite ends of a busbar that contains loads, the sum of 125 percent of the power source(s) output circuit current and the rating of the overcurrent device protecting the busbar shall not exceed 120 percent of the ampacity of the busbar. The busbar shall be sized for the loads connected in accordance with Article 220. A permanent warning label shall be applied to the distribution equipment adjacent to the back-fed breaker from the power source that displays the following or equivalent wording:

   **WARNING:**

   POWER SOURCE OUTPUT CONNECTION —

   DO NOT RELOCATE THIS OVERCURRENT DEVICE.

   The warning sign(s) or label(s) shall comply with 110.21(B).

   c. The sum of the ampere ratings of all overcurrent devices on panelboards, both load and supply devices, excluding the rating of the overcurrent device protecting the busbar, shall not exceed the ampacity of the busbar. The rating of the overcurrent device protecting the busbar shall not exceed the rating of the busbar. Permanent warning labels shall be applied to distribution equipment displaying the following or equivalent wording:

   **WARNING:**

   THIS EQUIPMENT FED BY MULTIPLE SOURCES.

   TOTAL RATING OF ALL OVERCURRENT DEVICES EXCLUDING MAIN SUPPLY OVERCURRENT DEVICE SHALL NOT EXCEED AMPACITY OF BUSBAR.

   The warning sign(s) or label(s) shall comply with 110.21(B).

   d. Connections shall be permitted on multiple-ampacity busbars or center-fed panelboards where designed under engineering supervision that includes fault studies and busbar load calculations.

**Statement of Problem and Substantiation for Public Comment**

This comment is mainly editorial, with the goal of having the code better communicate the requirements in section 705.12(D)(2)(2).
However it also contains a technical change which allows the requirements to comprehensively cover types of installations that are neglected by the current language.

The original language of 705.12(2)(2) from the 2014 code, as well as the First Draft language, can be easily misinterpreted as requiring the ampacity of a tap conductor to be the sum of the minimum requirements of 705.60 and 240.21(B), which is much larger than necessary. While the phrase "as calculated in 240.21(B)" seems intended to apply to the entire sum, it is not properly placed grammatically so as to make this clear and certain. This leaves many readers trying to interpret the meaning of phrase "the rating of the overcurrent device protecting the feeders as calculated in 240.21(B)". It is not entirely insensible to interpret that phrase as meaning the minimum requirements of 240.21(B). Thus some readers add the minimum requirements of the two sections together.

The new language proposed in this comment clears up any potential confusion about how 240.21(B) is to be followed. It uses the term 'tap conductors' properly as defined in 240.21(B). And by referring to an 'assumed rating', which is a sum more clearly defined in this section, it clears up which number is supposed to be used for 240.21(B) calculations, and in what manner.

In addition, the proposed language covers installations that have multiple sources connected to the same feeder, whether by taps or in panelboards fed by the feeder, or both. The rules in 240.21(B) are designed to account for the amount of available fault current, and the intention of 705.12(2)(2) is to have the fault current from all sources considered. However, the current First Draft language (like the 2014 code) assumes that the tap is the only non-primary source connection to the feeder. And yet a system could have one or more sources connected by taps, plus one or more sources connected with circuit breakers in downstream panelboards. There is no prohibition on such setups, nor should there be, but the First Draft language offers no guidance on such cases. By changing the relevant sum to include "all other sources that can supply additional fault current to the feeder", the new language concisely covers even the most complicated of real-world possibilities. All sources of fault current will be considered when sizing tap conductors.

Finally, in case the minimum size requirements of 240.21(B) are not clear because they refer to a 'load', the language proposed in this comment retains the minimum size requirements of 705.60.

In summary, I believe the language I've proposed here better communicates the intentions of CMP4 with respect to 705.12(D)(2)(2), while extending those intentions as much as possible to all conceivable installations.

Zip:
Submittal Date: Wed Sep 23 23:12:18 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-997-NFPA 70-2015
Statement: The first paragraph is revised to match the text in 705.12.

The last sentence of the paragraph on Taps is deleted, and the concept moved to 705.60, which is more appropriate.

A new item (2)(3)(d) is added to permit connections to center-fed panels in dwellings at either end while maintaining the 120 percent rule.

(5) is revised for clarity.
Public Comment No. 1356-NFPA 70-2015 [ Section No. 705.12(D)(2) ]

(2) Bus or Conductor Ampere Rating.

One hundred twenty-five percent of the power source output circuit current shall be used in ampacity calculations for the following:

(1) Feeders. Where the power source output connection is made to a feeder at a location other than the opposite end of the feeder from the primary source overcurrent device, that portion of the feeder on the load side of the power source output connection shall be protected by one of the following:

   (2) The feeder ampacity shall be not less than the sum of the primary source overcurrent device and 125 percent of the power source output circuit current.

   (3) An overcurrent device on the load side of the power source connection shall be rated not greater than the ampacity of the feeder.

(4) Taps. In systems where power source output connections are made at feeders, any taps shall be sized based on the sum of 125 percent of the power source(s) output circuit current and the rating of the overcurrent device protecting the feeder conductors as calculated in 240.21(B). Power source output circuit conductors, where smaller than the feeder conductors, shall be sized to carry not less than the larger of 705.60 or 240.21(B).

(5) Busbars. One of the methods that follows shall be used to determine the ratings of busbars in panelboards.

   (a) The sum of 125 percent of the power source(s) output circuit current and the rating of the overcurrent device protecting the busbar shall not exceed the ampacity of the busbar.

      Informational Note: This general rule assumes no limitation in the number of the loads or sources applied to busbars or their locations.

   (b) Where two sources, one a primary power source and the other another power source, are located at opposite ends of a busbar that contains loads, the sum of 125 percent of the power source(s) output circuit current and the rating of the overcurrent device protecting the busbar shall not exceed 120 percent of the ampacity current rating of the busbar. The busbar shall be sized for the loads connected in accordance with Article 220. A permanent warning label shall be applied to the distribution equipment adjacent to the back-fed breaker from the power source that displays the following or equivalent wording:

      WARNING:

      POWER SOURCE OUTPUT CONNECTION —

      DO NOT RELOCATE THIS OVERCURRENT DEVICE.

      The warning sign(s) or label(s) shall comply with 110.21(B).

   (c) The sum of the ampere ratings of all overcurrent devices on panelboards, both load and supply devices, excluding the rating of the overcurrent device protecting the busbar, shall not exceed the ampacity of the busbar. The rating of the overcurrent device protecting the busbar shall not exceed the rating of the busbar. Permanent warning labels shall be applied to distribution equipment displaying the following or equivalent wording:

      WARNING:

      THIS EQUIPMENT FED BY MULTIPLE SOURCES.

      TOTAL RATING OF ALL OVERCURRENT DEVICES

      EXCLUDING MAIN SUPPLY OVERCURRENT DEVICE

      SHALL NOT EXCEED AMPACITY OF BUSBAR.

      The warning sign(s) or label(s) shall comply with 110.21(B).

   (d) A connection at either end, but not both ends, of a center-fed panelboard shall be permitted where the rating of the overcurrent device does not exceed 120 percent of the current rating of the busbar. Connections shall be permitted on multiple-ampacity busbars or center-fed panelboards where designed under engineering supervision that includes available fault studies, current and busbar load calculations.

Statement of Problem and Substantiation for Public Comment
This is another option for the wording related to busbars in 705.12(D). This wording was recommended by Fred Hartwell as a way to simply allow center-fed panels to have a source connection. His explanation follows in a quote from an email he composed:

I think there is a fundamental misunderstanding of the 100% rule versus the 120% rule that pervades some current NEC requirements in 705.12(D) as well as the Wiles articles, which I have now reread more carefully than I should have when they first came out.

First, the 120% rule has nothing to do with busbar overloading. I can take a panelboard bus and protect opposite ends at 100% of rating (thus, connect it to sources at 200% of its rating), and never subject it to more amperes than its ampacity would allow. For example, consider a 200A bus with 200A supply circuit breakers arranged at opposite ends. No segment of the intervening busbars will see over 200A of current. If we had 250A of load connected to this busbar, there are two possibilities: Either one end receives over 200A, or not. If over 200A comes in from one side, then that side trips and regular conditions apply from the other end. If less than 200A comes in from one side, then the remaining current comes in from the other side which subtracts from the current needed from the first side. The 200A number cannot be exceeded in practice.

Second, even though the busbars could not be overloaded in terms of ampacity, the panelboard as an entity can be overloaded in terms of power delivered with any multiple sources of supply totaling above 100% of the rating for which it was tested. In the above example, the 200A bus assembly delivers 400A times voltage times applicable power factor in the form of power. My understanding, and this goes back to that cell phone conversation with the former CMP 9 NEMA rep I elaborated on at length in one of our previous conversations, is that this power density provides an overall heating effect that the panelboard manufacturers have not designed for. The 120% rule should be understood, therefore, as an allowable fudge factor that can be applied due to concerns about practicalities and the knowledge that there doesn’t seem to be any loss experience to challenge it. I am looking at language that allows the 120% rule to be extended to a center-fed panelboard even though the 100% protection rule has an academic potential of being violated in some minor way unlikely to be experienced in the real world.

Resolution: SR-997-NFPA 70-2015
Statement: The first paragraph is revised to match the text in 705.12.
The last sentence of the paragraph on Taps is deleted, and the concept moved to 705.60, which is more appropriate.
A new item (2)(3)(d) is added to permit connections to center-fed panels in dwellings at either end while maintaining the 120 percent rule.
(5) is revised for clarity.
Public Comment No. 1079-NFPA 70-2015 [Section No. 705.12(D)(5) ]

(5) Fastening.
Listed plug-in-type circuit breakers backfed from interactive inverters or other electric power sources that are listed and identified as interactive shall be permitted to omit the additional fastener normally required by 408.36(D) for such applications.

Statement of Problem and Substantiation for Public Comment
This section is now a little problematic. The allowance for not requiring fastening is based on the requirement that utility interactive inverters shut down on loss of utility power. Is saying "listed and identified as interactive" enough to ensure that the electric power source will shut down on loss of utility power? I'm not sure the term "interactive" will force that compliance.

Since the term "inverter" has been removed elsewhere in 705.12(D) is should also be removed from 705.12(D)(5) and electric power source will encompass it.

Statement: The first paragraph is revised to match the text in 705.12.

The last sentence of the paragraph on Taps is deleted, and the concept moved to 705.60, which is more appropriate.

A new item (2)(3)(d) is added to permit connections to center-fed panels in dwellings at either end while maintaining the 120 percent rule.

(5) is revised for clarity.
Disconnect Device.

The disconnecting means for ungrounded conductors shall consist of a manually or power operable switch(es) or circuit breaker(s) with the following features:

1. Located where readily accessible
2. Externally operable without exposing the operator to contact with live parts and, if power operable, of a type that could be opened by hand in the event of a power-supply failure
3. Plainly indicating whether in the open (off) or closed (on) position
4. Having ratings not less than the load to be carried and the fault current to be interrupted. For disconnect equipment energized from both sides, a marking shall be provided to indicate that all contacts of the disconnect equipment might be energized.
   
   Informational Note to (4): In parallel generation systems, some equipment, including knife blade switches and fuses, is likely to be energized from both directions. See 240.40.

5. Simultaneous disconnect of all ungrounded conductors of the circuit
6. Capable of being locked in the open (off) position

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs the panel to reconsider the wording of the section and adjust as necessary for proper grammar and clarity.

Submittal Date: Tue Sep 29 12:25:15 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-998-NFPA 70-2015
Statement: The revision makes several editorial corrections.

The sentence related to ratings was revised to correlate with actions in Article 690.

The reference to 690.13(B) was added to ensure consistent wording of signs.

The reference to 110.25 was added for the lockable feature.
705.23 Interactive System Disconnecting Means.
Means shall be provided in a readily accessible location, to disconnect the interactive system from all wiring systems including power systems, energy storage systems, and utilization equipment and its associated premises wiring.

Statement of Problem and Substantiation for Public Comment

The purpose to add the phrase "readily accessible location" to the first revision is for clarity in the requirement to indicate that those requisite to operate the disconnecting means can access it quickly for operation without climbing over, or removing obstacles or resort to portable ladders, etc.

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-999-NFPA 70-2015
Statement: This action adds clarity in the requirement to indicate that those required to operate the disconnecting means can access it quickly for operation without climbing over, or removing obstacles or resort to portable ladders, etc. This also correlates with 690.13.
705.31 Location of Overcurrent Protection.

Overcurrent protection for electric power production source conductors, connected to the supply side of the service disconnecting means in accordance with 705.12(A), shall be located within 3 m (10 ft) of the point where the electric power production source conductors are connected to the service.

Informational Note: This overcurrent protection protects against short-circuit current supplied from the primary source(s) of electricity.

Exception: Where the overcurrent protection for the power production source is located more than 3 m (10 ft) from the point of connection for the electric power production source to the service, cable limiters or current-limited circuit breakers for each ungrounded conductor shall be installed at the point where the electric power production conductors are connected to the service.

Statement of Problem and Substantiation for Public Comment

I agree with the PI. Service entrance conductors are by definition not protected by NEC for over current. Art 705.31 was added to the 2014 NEC according to the substantiation, "These unprotected conductors from the service entrance equipment to the remote disconnect with overcurrent protection are a safety hazard since they do not have adequate short-circuit current protection." But the same can be said of any service entrance conductors allowed in Art 230. Why hold these particular service entrance conductors to a higher standard than all other service entrance conductors?

In the resolution to this PI the CMP wrote, "Electric power production source conductors differ from service conductors by the definition in Article 100."

I point out that "Electric power production source conductors" are not defined in Art 100. They are no different than service entrance conductors from the utility. So far no one has indicated a specific hazard from service entrance conductors in Art 750 that are different than those in Art 230. If these service extract conductors require overcorrect protection then we need to apply the same logic to service entrance conductors from the utility and require they be protected also.

Organization: HAMON ENGINEERING INC
Street Address:
City:
State:
Zip:
Submittal Date: Wed Sep 23 18:32:35 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: There is not sufficient substantiation to delete the entire section. The section address a level of protection on conductors from an alternative power source that are permitted to be smaller than the service entrance conductors and yet subject to the same fault currents.
705.65 Overcurrent Protection.

(A) Circuits and Equipment.

Inverter input circuits, inverter output circuits, and storage battery circuit conductors and equipment shall be protected in accordance with the requirements of Article 240. Circuits connected to more than one electrical source shall have overcurrent devices located so as to provide overcurrent protection from all sources.

Exception: An overcurrent device shall not be required for circuit conductors sized in accordance with 705.60(B) and located where one of the following applies:

(1) There are no external sources such as parallel-connected source circuits, batteries, or backfeed from inverters.

(2) The short-circuit currents from all sources do not exceed the ampacity of the conductors.

Informational Note: Possible backfeed of current from any source of supply, including a supply through an inverter into the inverter output circuit and inverter source circuits, is a consideration in determining whether adequate overcurrent protection from all sources is provided for conductors and modules.

(B) Power Transformers.

Overcurrent protection for a transformer with a source(s) on each side shall be provided in accordance with 450.3 by considering first one side of the transformer, then the other side of the transformer, as the primary.

Exception: A power transformer with a current rating on the side connected toward the interactive inverter output that is not less than the rated continuous output current of the inverter shall be permitted without overcurrent protection from that source.

Statement of Problem and Substantiation for Public Comment

The correlating Committee directs further consideration be given to the comments expressed in voting on FR 3663.

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-1000-NFPA 70-2015
Statement: “Intentionally islanded systems” were changed to “microgrid systems” for consistency.

References to stand-alone systems were eliminated, as they are now addressed in Article 710.

The disconnecting means section was deleted as it is addressed elsewhere.

An informational note was added to explicitly indicate that MID functionality can be included in other devices.
705.170 - Island Interconnection Devices (IID).

1. An IID shall be required for any connection between an intentionally islanded or stand-alone system and a primary power source.

2. Interconnection devices shall be listed, or field labeled, as suitable for the intended interconnection application.

3. Interconnection devices shall have sufficient number of overcurrent devices located so as to provide overcurrent protection from all sources.

Statement of Problem and Substantiation for Public Comment

The interconnection function is already addressed in existing requirements and standards, and should not be duplicated in this manner. UL standards for interactive product address the specific considerations that must be addressed for this application and listed Interactive inverters which manage the interconnection to the area EPS are available from numerous manufacturers, yet these devices are not marked as being "Island Interconnection Devices" and so would not appear to comply with this requirement. In addition, there is no functional requirement for an intentionally islanded system to perform a seamless transfer, other than customer convenience; a listed manual double throw safety switch would provide the same level of safety, albeit at a lower level of convenience, but is not marked as an Island Interconnection Device. Overcurrent protection, disconnecting means, synchronizing means and the protection from multiple sources are addressed elsewhere in this article, so there is no benefit from adding this new requirement, only added complexity and potential confusion to AHJs and installers.

Statement: "Intentionally islanded systems" were changed to "microgrid systems" for consistency.

References to stand-alone systems were eliminated, as they are now addressed in Article 710.

The disconnecting means section was deleted as it is addressed elsewhere.

An informational note was added to explicitly indicate that MID functionality can be included in other devices.
Public Comment No. 1209-NFPA 70-2015 [Section No. 705.170]

705.170 Island Interconnection Devices (IID).

(1) An IID shall be required for any connection between an intentionally islanded or stand-alone system and a primary power source.

Exception: where an interactive inverter, ESS or other device listed for interactive operation incorporates the interconnection function.

(1) Interconnection devices shall be listed, or field labeled, as suitable for the intended interconnection application.

(2) Overcurrent protection for interconnection devices shall have sufficient number of overcurrent devices located so as to provide overcurrent protection from all sources, be in accordance with 705.30.

Statement of Problem and Substantiation for Public Comment

The proposed 705.170 Island Interconnection Device (IID) does not add value and should be rejected, per comment 1208. However, if the CMP disagrees and sees merit in the concept, this section should be revised to allow available listed interactive product which manage the utility interconnection as part of their listed function to be used. Overcurrent protection requirements for multiple sources is already addressed in 705.30 in a more comprehensive manner, this section should simply reference that.

NOTE: Terraview inadvertently renumbered the requirements, this was not an intentional change.

Public Comment No. 1015-NFPA 70-2015 [Section No. 705.175]

705.175 Stand-Alone Wiring Systems.
This section relates to stand-alone systems operating in stand-alone mode.
Premises wiring systems shall be adequate to meet the requirements of this Code for similar installations supplied by a feeder or service. The wiring on the supply side of the building or structure disconnecting means shall comply with the requirements of this Code, except as modified by 705.175(A) through (F).

(A) Supply Output.
Power supply to premises wiring systems shall be permitted to have less capacity than the calculated load. The capacity of the stand-alone supply shall be equal to or greater than the load posed by the largest single utilization equipment connected to the system. Calculated general lighting loads shall not be considered as a single load.

(B) Sizing and Protection.
The circuit conductors between a stand-alone source and a building or structure disconnecting means shall be sized based on the sum of the output ratings of the stand-alone sources.

(C) Single 120-Volt Supply.
Stand-alone systems shall be permitted to supply 120 volts to single-phase, 3-wire, 120/240-volt service equipment or distribution panels where there are no 240-volt outlets and where there are no multiwire branch circuits. In all installations, the sum of the ratings of the power sources shall be less than the rating of the neutral bus in the service equipment. This equipment shall be marked with the following words or equivalent:
WARNING:
SINGLE 120-VOLT SUPPLY. DO NOT CONNECT MULTIWIRE BRANCH CIRCUITS!
The warning sign(s) or label(s) shall comply with 110.21(B).

(D) Energy Storage or Backup Power System Requirements.
Energy storage or backup power supplies are not required.

(E) Back-Fed Circuit Breakers.
Plug-in type back-fed circuit breakers connected to an interconnected supply shall be secured in accordance with 408.36(D). Circuit breakers marked "line" and "load" shall not be back-fed.

(F) Voltage and Frequency Control.
The stand-alone supply shall be controlled so that voltage and frequency remain within suitable limits for the connected loads.

Statement of Problem and Substantiation for Public Comment
This commentor agrees with moving these requirements out of 690 and into 705, where they will apply to all interconnected systems. However, the title should be revised to more clearly indicate the issues being addressed.

Organization: OUTBACK POWER TECHNOLOGIES
Street Address:
City:
State:
Zip:
Submittal Date: Wed Sep 23 00:34:19 EDT 2015

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-987-NFPA 70-2015
Statement: This panel action addresses the operating parameters for electric power production sources in Stand Alone Mode.

The requirements for stand-alone systems do not fit well in 705 (interconnected systems). For stand-alone systems to remain at the end of 705, the scope and title of 705 would have to be changed to encompass both interconnected and non-interconnected systems. Creating a new article makes sense, and is supported by the original proposers and the CC.

An NEC Article for stand-alone systems is important as, while these requirements exist in Articles 690, 692 and 694 of the 2014 Code, they should apply to other power sources such as engine generators. The hazards of feeding multi-wire branch circuits with single-phase 120V are the same whether the source is a generator or an inverter.
705.175  Wiring, Stand-Alone, Systems. [also move whole section to new Article 710]

This section relates to stand-alone systems operating in stand-alone mode.

Premises wiring systems shall be adequate to meet the requirements of this Code for similar installations supplied by a feeder or service. The wiring on the supply side of the building or structure disconnecting means shall comply with the requirements of this Code, except as modified by 705.175(A) through (F).

(A) Supply Output.

Power supply to premises wiring systems shall be permitted to have less capacity than the calculated load. The capacity of the stand-alone supply shall be equal to or greater than the load posed by the largest single utilization equipment connected to the system. Calculated general lighting loads shall not be considered as a single load.

(B) Sizing and Protection.

The circuit conductors between a stand-alone source and a building or structure disconnecting means shall be sized based on the sum of the output ratings of the stand-alone sources.

(C) Single 120-Volt Supply.

Stand-alone systems shall be permitted to supply 120 volts to single-phase, 3-wire, 120/240-volt service equipment or distribution panels where there are no 240-volt outlets and where there are no multiwire branch circuits. In all installations, the sum of the ratings of the power sources shall be less than the rating of the neutral bus in the service equipment. This equipment shall be marked with the following words or equivalent:

**WARNING:**

SINGLE 120-VOLT SUPPLY. DO NOT CONNECT MULTIWIRE BRANCH CIRCUITS!

The warning sign(s) or label(s) shall comply with 110.21(B).

(D) Energy Storage or Backup Power System Requirements.

Energy storage or backup power supplies are not required.

(E) Back-Fed Circuit Breakers.

Plug-in type back-fed circuit breakers connected to an interconnected supply shall be secured in accordance with 408.36(D). Circuit breakers marked “line” and “load” shall not be back-fed.

(F) Voltage and Frequency Control.

The stand-alone supply shall be controlled so that voltage and frequency remain within suitable limits for the connected loads.

---

**Statement of Problem and Substantiation for Public Comment**

The title of this section should be "Stand-alone systems".

Stand-alone systems do not belong in 705, as acknowledged by the TCC report.

A working group should be formed to draft a new Article 710 Stand-Alone Systems based on this section from FR 705.175

Some content for this can be extracted from the original proposal for 710 Microgrids (PI 4026).

To be clear, all interconnection aspects of intentional island / microgrid behavior will remain in 705.

The stand-alone (forming 710) language is essentially the same as what has been removed from 690, 690 and 694.

There is general consensus that utilization aspects of renewable and off-grid power systems should not be in energy source articles such as 690.

We recommend that Article 710 be kept in CMP4 as it is a natural companion to 705, and the members of CMP4 are already familiar with its content as it came from 690, 694 etc.

Utility industry members of our WG have said:

We see [stand-alone systems] as several photovoltaic panels with batteries operating signs, lights, point-of-sale parking, and instrumentation. In addition, there are people with installations who wish to be “off-grid” as an individual choice. The utility industry supports the concept for those types of connections. However, our position is that if a “stand-alone” system does wish to interconnect with the AC system, then the requirements of Article 705 would apply. We also support the concept of an interconnected system that complies with Article 705 to re-configure to a stand-alone system for any operational purpose.

There is some disagreement over the use of the term "microgrid", vs "intentional island".

We plan to build consensus on this and other issues among our members in a working group prior to the November meeting.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-987-NFPA 70-2015
Statement: This panel action addresses the operating parameters for electric power production sources in Stand Alone Mode.

The requirements for stand-alone systems do not fit well in 705 (interconnected systems). For stand-alone systems to remain at the end of 705, the scope and title of 705 would have to be changed to encompass both interconnected and non-interconnected systems. Creating a new article makes sense, and is supported by the original proposers and the CC.

An NEC Article for stand-alone systems is important as, while these requirements exist in Articles 690, 692 and 694 of the 2014 Code, they should apply to other power sources such as engine generators. The hazards of feeding multi-wire branch circuits with single-phase 120V are the same whether the source is a generator or an inverter.
Public Comment No. 349-NFPA 70-2015 [Section No. 705.175]

705.175 Stand-alone Wiring Systems.
This section relates to stand-alone Premises wiring systems operating in stand-alone mode . Premises wiring systems shall be adequate to meet the requirements of this Code for similar installations supplied by a feeder or service. The wiring on the supply side of the building or structure disconnecting means shall comply with the requirements of this Code, except as modified by 705.175(A) through (F).

(A) Supply Output.
Power supply to premises wiring systems shall be permitted to have less capacity than the calculated load. The capacity of the stand-alone supply shall be equal to or greater than the load posed by the largest single utilization equipment connected to the system. Calculated general lighting loads shall not be considered as a single load.

(B) Sizing and Protection.
The circuit conductors between a stand-alone source and a building or structure disconnecting means shall be sized based on the sum of the output ratings of the stand-alone sources.

(C) Single 120-Volt Supply.
Stand-alone systems shall be permitted to supply 120 volts to single-phase, 3-wire, 120/240-volt service equipment or distribution panels where there are no 240-volt outlets and where there are no multiwire branch circuits. In all installations, the sum of the ratings of the power sources shall be less than the rating of the neutral bus in the service equipment. This equipment shall be marked with the following words or equivalent:

WARNING: SINGLE 120-VOLT SUPPLY. DO NOT CONNECT MULTIWIRE BRANCH CIRCUITS!
The warning sign(s) or label(s) shall comply with 110.21(B).

(D) Energy Storage or Backup Power System Requirements.
Energy storage or backup power supplies are not required.

(E) Back-Fed Circuit Breakers.
Plug-in type back-fed circuit breakers connected to an interconnected supply shall be secured in accordance with 408.36(D). Circuit breakers marked "line" and "load" shall not be back-fed.

(F) Voltage and Frequency Control.
The stand-alone supply shall be controlled so that voltage and frequency remain within suitable limits for the connected loads.

Statement of Problem and Substantiation for Public Comment

Revisions as suggested by Mr. Roger McDaniel in comment on affirmative vote.

Statement of Problem and Substantiation for Public Comment

This commentor agrees with moving these requirements out of 690 and into 705, where they will apply to all interconnected systems. However, the requirements should apply not only stand-alone systems but also to multi-mode systems operating in stand-alone mode.

Article 706  Energy Storage Systems

Part I.  General

706.1  Scope.
This article applies to all permanently installed energy storage systems (ESS) that may be stand-alone or interactive with other electric power production sources.

Informational Note: The following standards are frequently referenced for the installation of energy storage systems:

1. NFPA 111-2013, Standard on Stored Electrical Energy Emergency and Standby Systems
2. IEEE 484-2008, Recommended Practice for Installation Design and Installation of Vented Lead-Acid Batteries for Stationary Applications
3. IEEE 485-1997, Recommended Practice for Sizing Vented Lead-Acid Storage Batteries for Stationary Applications
4. IEEE 1145-2007, Recommended Practice for Installation and Maintenance of Nickel-Cadmium Batteries for Photovoltaic (PV) Systems
5. IEEE 1187-2002, Recommended Practice for Installation Design, and Installation of Valve-Regulated Lead-Acid Batteries for Stationary Applications
6. IEEE 1578-2007, Recommended Practice for Stationary Battery Spill Containment and Management
8. UL 1973, Batteries for Use in Light Electric Rail (LER) Applications and Stationary Applications
9. UL Subject 2436, Spill Containment For Stationary Lead Acid Battery Systems
10. UL 1989, Standby Batteries
11. UL 810A, Electrochemical Capacitors
12. UL Subject 9540, Safety of Energy Storage Systems and Equipment

706.2  Definitions.

Battery.  
Two or more cells connected together electrically in series, in parallel, or a combination of both to provide the required operating voltage and current levels.

Battery Terminal.  
That part of a cell, container, or battery to which an external connection is made (commonly identified as post, pillar, pole, or terminal post).

Cell.  
The basic electrochemical unit, characterized by an anode and a cathode, used to receive, store, and deliver electrical energy.

Container.  
A vessel that holds the plates, electrolyte, and other elements of a single unit, comprised of one or more cells, in a battery. It can be referred to as a jar or case.

Diversion Charge Controller.  
Equipment that regulates the charging process of an ESS by diverting power from energy storage to direct-current or alternating-current loads or to an interconnected utility service.

Electrochemical Battery.  
A battery comprised of one or more rechargeable cells of the lead-acid, nickel-cadmium, or other rechargeable electrochemical types.

Electrolyte.  
The medium that provides the ion transport mechanism between the positive and negative electrodes of a cell.

Energy Storage System (ESS).  
A device or more than one device assembled together capable of storing energy for use at a future time. ESS(s) includes but is not limited to electrochemical storage devices (e.g., batteries), flow batteries, capacitors, and kinetic energy devices (e.g., flywheels and compressed air). These systems can have ac or dc output for utilization and can include inverters and converters to change stored energy into electrical energy.

Energy storage systems where the energy storage devices such as cells, batteries, or modules and any necessary controls, ventilation, illumination, fire suppression, or alarm systems are assembled, installed, and packaged into a singular energy storage container or unit.

Informational Note: Self-contained systems will generally be manufactured by a single entity, tested and listed to safety standards relevant to the system, and readily connected on site to the electrical system and in the case of multiple systems to each other.

Energy Storage System, Pre-engineered of Matched Components.

Energy storage systems that are not self-contained systems but instead are provided as separate components of a system by a singular entity that are matched and intended to be assembled as an energy storage system at the system installation site.

Informational Note: Pre-engineered systems of matched components for field assembly as a system will generally be designed by a single entity and comprised of components that are tested and listed separately or as an assembly to safety standards relevant to the component and readily assembled on site as a system and connected on site to the electrical system.

Energy Storage System, Other.

Energy storage systems that are not self-contained or pre-engineered systems of matched components but instead are composed of individual components assembled as a system.

Informational Note: Other systems will generally be comprised of different components combined on site to create an ESS. Those components would generally be tested and listed to safety standards relevant to the application.

Flow Battery.

An energy storage device similar to a fuel cell that stores its active materials in the form of two electrolytes external to the reactor interface. When in use, the electrolytes are transferred between reactor and storage tanks.

Informational Note: Two commercially available flow battery technologies are zinc bromine and vanadium redox, sometimes referred to as pumped electrolyte ESS.

Intercell Connector.

An electrically conductive bar or cable used to connect adjacent cells.

Inter-tier Connector.

In an electrochemical battery system, an electrical conductor used to connect two cells on different tiers of the same rack or different shelves of the same rack.

Inverter Input Circuit.

Conductors between the inverter and the ESS in stand-alone and multimode inverter systems.

Inverter Output Circuit.

Conductors between the inverter and another electric power production source, such as a utility for an electrical production and distribution network.

Inverter Utilization Output Circuit.

Conductors between the multimode or standalone inverter and utilization equipment.

Nominal Voltage (Battery or Cell).

The value assigned to a cell or battery of a given voltage class for the purpose of convenient designation. The operating voltage of the cell or battery may vary above or below this value.

Sealed Cell or Battery.

A cell or battery that has no provision for the routine addition of water or electrolyte or for external measurement of electrolyte specific gravity.

Informational Note: Some cells that are considered to be sealed under conditions of normal use, such as valve-regulated lead-acid or some lithium cells, contain pressure relief valves.

706.3 Other Articles.

Wherever the requirements of other articles of this Code and Article 706 differ, the requirements of Article 706 shall apply. If the ESS is capable of being operated in parallel with a primary source(s) of electricity, the requirements in 705.6, 705.14, 705.16, 705.32, and 705.143 shall apply.

706.4 System Classification.

ESS shall be classified as one of the types described as follows:

(1) Self-contained ESS

Informational Note: Some self-contained systems may be listed.

(2) Pre-engineered of matched components ESS intended for field assembly as a system

(3) Energy storage system, other
706.5 Equipment.
Monitors and controls, switches and breakers, power conversion systems, inverters and transformers, energy storage devices, and other components of the energy storage system shall be listed for the intended application as a part of an energy storage system. Alternatively, prepackaged self-contained systems shall be permitted to be listed for the intended application as a complete energy storage system. Only inverters listed and identified as interactive shall be permitted on interactive systems.

706.6 Multiple Systems.
Multiple ESSs shall be permitted to be installed in or on a single building or structure.

706.7 Disconnecting Means.
(A) ESS Disconnecting Means.
A disconnecting means shall be provided for all ungrounded conductors derived from an ESS. A disconnecting means shall be readily accessible and located within sight of the ESS.

Informational Note: See 240.21(H) for information on the location of the overcurrent device for conductors.

(B) Remote Actuation.
Where controls to activate the disconnecting means of an ESS are not located within sight of the system, the disconnecting means shall be capable of being locked in the open position, in accordance with 110.25, and the location of the controls shall be field marked on the disconnecting means.

(C) Busway.
Where a dc busway system is installed, the disconnecting means shall be permitted to be incorporated into the busway.

(D) Notification.
The disconnecting means shall be legibly marked in the field. A label with the marking shall be placed in a conspicuous location near the ESS if a disconnecting means is not provided. The marking shall be of sufficient durability to withstand the environment involved and shall include the following:

1. Nominal ESS voltage
2. Maximum available fault current derived from the ESS
3. Arc flash risk assessment at the disconnecting means
4. Date the calculation was performed

Informational Note: Battery equipment suppliers can provide information about short-circuit current on any particular battery model. NFPA 70E provides requirements for arc flash risk assessment.

(E) Partitions and Distance.
Where energy storage device input and output terminals are more than 1.5 m (5 ft) from connected equipment, or where the circuits from these terminals pass through a wall or partition, the installation shall comply with the following:

1. A disconnecting means and overcurrent protection shall be provided at the energy storage device end of the circuit. Fused disconnecting means or circuit breakers shall be permitted to be used.
2. Where fused disconnecting means are used, the line terminals of the disconnecting means shall be connected toward the energy storage device terminals.
3. Overcurrent devices or disconnecting means shall not be installed in energy storage device enclosures where explosive atmospheres can exist.
4. A second disconnecting means located at the connected equipment shall be installed where the disconnecting means required by 706.7(E) (1) is not within sight of the connected equipment.
5. Where the energy storage device disconnecting means is not within sight of the ESS disconnecting means, placards or directories shall be installed at the locations of all disconnecting means indicating the location of all disconnecting means.

706.8 Connection to Other Energy Sources.
Connection to other energy sources shall comply with the requirements of 705.12.

(A) Load Disconnect.
A load disconnect that has multiple sources of power shall disconnect all energy sources when in the off position.

(B) Identified Interactive Equipment.
Only inverters and ac modules listed and identified as interactive shall be permitted on interactive systems.

(C) Loss of Interactive System Power.
An inverter in an interactive energy storage system shall automatically de-energize its output to the connected electrical production and distribution network upon loss of voltage in that system and shall remain in that state until the electrical production and distribution network voltage has been restored. A normally interactive energy storage system shall be permitted to operate as a stand-alone system to supply loads that have been disconnected from electrical production and distribution network sources.
(D) Unbalanced Interconnections.

Unbalanced connections between an energy storage system and electric power production sources shall be in accordance with 705.100.

(E) Point of Connection.

The point of connection between an energy storage system and electric power production sources shall be in accordance with 705.12.

706.10 Energy Storage System Locations.

Battery locations shall conform to 706.10(A), (B), and (C).

(A) Ventilation.

Provisions appropriate to the energy storage technology shall be made for sufficient diffusion and ventilation of any possible gases from the storage device, if present, to prevent the accumulation of an explosive mixture. A pre-engineered or self-contained ESS shall be permitted to provide ventilation in accordance with the manufacturer’s recommendations and listing for the system.

Informational Note No. 1: See NFPA 1-2015, Fire Code, Chapter 52, for ventilation considerations for specific battery chemistries.

Informational Note No. 2: Some storage technologies do not require ventilation.

Informational Note No. 4: Fire protection considerations are addressed in NFPA 1-2015, Fire Code.

(B) Guarding of Live Parts.

Guarding of live parts shall comply with 110.27.

(C) Spaces About ESS Components.

Spaces about the ESS shall comply with 110.26. Working space shall be measured from the edge of the ESS modules, battery cabinets, racks, or trays. For battery racks, there shall be a minimum clearance of 25 mm (1 in.) between a cell container and any wall or structure on the side not requiring access for maintenance. ESS modules, battery cabinets, racks, or trays shall be permitted to contact adjacent walls or structures, provided that the battery shelf has a free air space for not less than 90 percent of its length. Pre-engineered and self-contained ESSs shall be permitted to have working space between components within the system in accordance with the manufacturer’s recommendations and listing of the system.

Informational Note: Additional space is often needed to accommodate ESS equipment hoisting equipment, tray removal, or spill containment.

(D) Egress.

A personnel door(s) intended for entrance to and egress from rooms designated as ESS rooms shall open in the direction of egress and shall be equipped with listed panic hardware.

(E) Illumination.

Illumination shall be provided for working spaces associated with ESS and their equipment and components. Luminaires shall not be controlled by automatic means only. Additional luminaires shall not be required where the work space is illuminated by an adjacent light source. The location of luminaires shall not do either of the following:

1. Expose personnel to energized system components while performing maintenance on the luminaires in the system space
2. Create a hazard to the system or system components upon failure of the luminaire

706.11 Directory.

ESS shall be indicated by 706.11(A) and (B). The markings or labels shall be in accordance with 110.21(B).

(A) Directory.

A permanent plaque or directory denoting all electric power sources on or in the premises shall be installed at each service equipment location and at locations of all electric power production sources capable of being interconnected.

Exception: Installations with large numbers of power production sources shall be permitted to be designated by groups.

(B) Facilities with Stand-Alone Systems.

Any structure or building with an ESS that is not connected to a utility service source and is a stand-alone system shall have a permanent plaque or directory installed on the exterior of the building or structure at a readily visible location acceptable to the authority having jurisdiction. The plaque or directory shall indicate the location of system disconnecting means and that the structure contains a stand-alone electrical power system.

Part II. Circuit Requirements

706.20 Circuit Sizing and Current.

(A) The maximum current for the specific circuit shall be calculated in accordance with 706.20(A)(1) through (A)(5).
(1) Nameplate Rated Circuit Current.
The nameplate(s) rated circuit current shall be the rated current indicated on the ESS nameplate(s) or system listing for
pre-engineered or self-contained systems of matched components intended for field assembly as a system.

(2) Inverter Output Circuit Current.
The maximum current shall be the inverter continuous output current rating.

(3) Inverter Input Circuit Current.
The maximum current shall be the continuous inverter input current rating when the inverter is producing rated power at the
lowest input voltage.

(4) Inverter Utilization Output Circuit Current.
The maximum current shall be the continuous inverter output current rating when the inverter is producing rated power at the
lowest input voltage.

(5) DC to DC Converter Output Current.
The maximum current shall be the dc-to-dc converter continuous output current rating.

(B) Conductor Ampacity and Overcurrent Device Ratings.
The ampacity of the feeder circuit conductors from the ESS(s) to the wiring system serving the loads to be serviced by the
system shall not be less than the greater of the (1) nameplate(s) rated circuit current as determined in accordance with
706.20(A) or (2) the rating of the ESS(s) overcurrent protective device(s).

(C) Ampacity of Grounded or Neutral Conductor.
If the output of a single-phase, 2-wire ESS output(s) is connected to the grounded or neutral conductor and a single ungrounded
conductor of a 3-wire system or of a 3-phase, 4-wire, wye-connected system, the maximum unbalanced neutral load current
plus the ESS(s) output rating shall not exceed the ampacity of the grounded or neutral conductor.

706.21 Overcurrent Protection.
(A) Circuits and Equipment.
Energy storage circuit conductors shall be protected in accordance with the requirements of Article 240. Protection devices for
ESS circuits shall be in accordance with the requirements of 706.11(B) through (F). Circuits shall be protected at the source
from overcurrent.

(B) Overcurrent Device Ampere Ratings.
Overcurrent protective devices, where required, shall be rated in accordance with Article 240 and the rating provided on
systems serving the ESS and shall be not less than 125 percent of the maximum currents calculated in 706.10(A) .

(C) Direct Current Rating.
Overcurrent protective devices, either fuses or circuit breakers, used in any dc portion of an ESS shall be listed and shall have
the appropriate voltage, current, and interrupting ratings.

(D) Prime Movers.
Overcurrent protection shall not be required for conductors from an ESS with a nominal voltage of 50 volts or less if these
conductors provide power for starting, ignition, or control of prime movers. Section 300.3 shall not apply to these conductors.

(E) Current Limiting.
A listed, current-limiting, overcurrent device shall be installed in each dc output circuit adjacent to the ESS.

(F) Fuses.
Means shall be provided to disconnect any fuses associated with ESS equipment and components when the fuse is energized
from both directions and is accessible to other than qualified persons. Switches, pullouts, or similar devices that are rated for the
application shall be permitted to serve as a means to disconnect fuses from all sources of supply.

706.22 Wiring from and Equipment Supplied by Energy Storage Systems.
Wiring and equipment supplied from ESS(s) and system components shall be subject to the applicable provisions of this Code
applying to wiring and equipment operating at the same voltage, unless otherwise permitted by this article.

706.23 Charge Control.
(A) General.
Provisions shall be provided to control the charging process of the ESS. All adjustable means for control of the charging
process shall be accessible only to qualified persons.

Informational Note: Certain types of energy storage equipment such as valve-regulated lead acid or nickel cadmium
can experience thermal failure when overcharged.

(B) Diversion Charge Controller.
(1) Sole Means of Regulating Charging.
An ESS employing a diversion charge controller as the sole means of regulating charging shall be equipped with a second
independent means to prevent overcharging of the storage device.
Circuits with Diversion Charge Controller and Diversion Load.

Circuits containing a diversion charge controller and a diversion load shall comply with the following:

1. The current rating of the diversion load shall be less than or equal to the current rating of the diversion load charge controller. The voltage rating of the diversion load shall be greater than the maximum ESS voltage. The power rating of the diversion load shall be at least 150 percent of the power rating of the charging source.

2. The conductor ampacity and the rating of the overcurrent device for this circuit shall be at least 150 percent of the maximum current rating of the diversion charge controller.

Systems using utility-interactive inverters to control energy storage state-of-charge by diverting excess power into the utility system shall comply with 706.23(B)(3)(a) and (B)(3)(b).

(a) These systems shall not be required to comply with 706.23(B)(2).

(b) These systems shall have a second, independent means of controlling the ESS charging process for use when the utility is not present or when the primary charge controller fails or is disabled.

Charge controllers and DC converters.

When charge controllers and other dc power converters that increase or decrease the output current or output voltage with respect to the input current or input voltage are installed the ampacity of the conductors in output circuits shall be based on the maximum rated continuous output current of the charge controller or converter for the selected output voltage range, and the voltage rating of the output circuits shall be based on the maximum voltage output of the charge controller or converter for the selected output voltage range.

Part III. Electrochemical Energy Storage Systems

Part III of this article applies to ESSs that are comprised of sealed and non-sealed cells or batteries or system modules that are comprised of multiple sealed cells or batteries.

706.30 Installation of Batteries.

Storage batteries associated with an ESS shall be installed in accordance with the provisions this article.

(A) Dwelling Units.

ESSs for dwellings shall be configured so as to operate at a voltage of 100 volts or less.

Exception: Where live parts are not accessible during routine ESS maintenance, an ESS voltage greater than 100 volts shall be permitted.

(B) Storage System Nonconductive Cases and Conductive Racks.

Flooded, vented lead-acid batteries where operating at more than 100 volts shall not use conductive cases or shall not be installed in conductive cases. Conductive racks used to support nonconductive cases shall be permitted where no rack material is located within 150 mm (6 in.) of the tops of the nonconductive cases.

Exception: This requirement shall not apply to any type of valve-regulated lead-acid (VRLA) battery or other types of sealed batteries that may require steel cases for proper operation.

Note: Parts VI and VII of Article 250 address exposed metal parts.

(C) Disconnection of Series Battery Circuits.

Battery circuits subject to field servicing, where operating at more than 100 volts, shall have provisions to disconnect the series-connected strings into segments of 100 volts or less for maintenance by qualified persons. Non–load-break bolted or plug-in disconnects shall be permitted.

(D) Storage System Maintenance Disconnecting Means.

ESS greater than 100 volts shall have a disconnecting means, accessible only to qualified persons, that disconnects the grounded circuit conductor(s) in the electrical storage system for maintenance. This disconnecting means shall not disconnect the grounded circuit conductor(s) for the remainder of any other electrical system. A non–load-break-rated switch shall be permitted to be used as a disconnecting means.

(E) Storage Systems of More Than 100 Volts.

On electrochemical ESS operating at more than 100 volts, the system shall be permitted to operate with ungrounded conductors, provided a ground-fault detector and indicator is installed to monitor for ground faults within the storage system.

706.31 Battery and Cell Terminations.

(A) Corrosion Prevention.

Antioxidant material suitable for the battery connection shall be used when recommended by the battery or cell manufacturer.

Informational Note: The battery manufacturer's installation and instruction manual can be used for guidance for acceptable materials.
Intercell and Intertier Conductors and Connections.

The ampacity of field-assembled intercell and intertier connectors and conductors shall be of such cross-sectional area that the temperature rise under maximum load conditions and at maximum ambient temperature shall not exceed the safe operating temperature of the conductor insulation or of the material of the conductor supports.

Informational Note: Conductors sized to prevent a voltage drop exceeding 3 percent of maximum anticipated load, and where the maximum total voltage drop to the furthest point of connection does not exceed 5 percent, may not be appropriate for all battery applications. IEEE 1375-2003, Guide for the Protection of Stationary Battery Systems, provides guidance for overcurrent protection and associated cable sizing.

Battery Terminals.

Electrical connections to the battery and the cable(s) between cells on separate levels or racks shall not put mechanical strain on the battery terminals. Terminal plates shall be used where practicable.

Flexible cables, as identified in Article 400, in sizes 2/0 AWG and larger shall be permitted within the battery enclosure from battery terminals to a nearby junction box where they shall be connected to an approved wiring method. Flexible battery cables shall also be permitted between batteries and cells within the battery enclosure. Such cables shall be listed and identified as moisture resistant. Flexible, fine-stranded cables shall only be used with terminals, lugs, devices, or connectors in accordance with 110.14.

Accessibility.

The terminals of all cells or multicell units shall be readily accessible for readings, inspection, and cleaning where required by the equipment design. One side of transparent battery containers shall be readily accessible for inspection of the internal components.

Battery Locations.

Electrochemical battery locations shall conform to 706.34(A), (B), and (C).

(A) Live Parts.

Guarding of live parts shall comply with 110.27.

(B) Top Terminal Batteries.

Where top terminal electrochemical energy storage devices are installed on tiered racks or on shelves of battery cabinets, working space in accordance with the storage equipment manufacturer’s instructions shall be provided between the highest point on a storage system component and the row, shelf, or ceiling above that point.

Informational Note No. 1: The installation instructions of the system component manufacturer typically define how much top working space is necessary for a particular system component. Informational Note No. 2: IEEE 1187 provides guidance for top clearance of VRLA batteries, which are the most commonly used battery in cabinets.

(C) Gas Piping.

Gas piping shall not be permitted in dedicated battery rooms or spaces dedicated to electrochemical ESS.

Vents.

(A) Vented Cells.

Each vented cell shall be equipped with a flame arrester.

Informational Note: A flame arrester is designed to prevent destruction of the cell due to ignition of gases within the cell by an external spark or flame under normal operating conditions.

(B) Sealed Cells.

Sealed battery or cells shall be permitted to be equipped with a pressure-release vent to prevent excessive accumulation of gas pressure.

Part III. Flow Battery Energy Storage Systems

The provisions Part IV apply to ESSs composed of or containing flow batteries.

General.

All electrical connections to and from the system and system components shall be in accordance with the applicable provisions of Article 692. The system and system components shall also meet the provisions of Parts I and II of this article. Unless otherwise directed by this article, flow battery ESS shall comply with the applicable provisions of Article 692.

Electrolyte Classification.

The electrolyte(s) that are acceptable for use in the batteries associated with the ESS shall be identified by name and chemical composition. Such identification shall be provided by readily discernable signage adjacent to every location in the system where the electrolyte can be put into or taken out of the system.

Electrolyte Containment.

Flow battery systems shall be provided with a means for electrolyte containment to prevent spills of electrolyte from the system. An alarm system is to be provided to signal an electrolyte leaks from the system. Electrical wiring and connections shall be located and routed in a manner that mitigates the potential for exposure to electrolytes.
706.43 Flow Controls.
Controls shall be provided to safely shut down the system in the event of electrolyte blockage such as a malfunctioning electrolyte pump or valve.

706.44 Pumps and Other Fluid Handling Equipment.
Pumps and other fluid handling equipment are to be rated/specifed suitable for exposure to the electrolytes.

Part V. Other Energy Storage Technologies
The provisions of Part V apply to ESSs using other technologies intended to store energy and when there is a demand for electrical power to use the stored energy to generate the needed power.

706.50 General.
All electrical connections to and from the system and system components shall be in accordance with the applicable provisions of this Code. Unless otherwise directed by this article, other energy storage technologies shall comply with the applicable provisions of Part III of Article 705.

Statement of Problem and Substantiation for Public Comment
The purpose of the NEC is not to be an instruction manual or educational textbook, informational note text removed was instructional and not needed to apply the code.

Public Comment No. 1712-NFPA 70-2015 [Definition: Battery Terminal.]

Battery Terminal.
That part of a cell, container, or battery to which an external connection is made (commonly identified as post, pillar, pole, or terminal post).

Statement of Problem and Substantiation for Public Comment

Deleting "Battery" from the title aligns this definition with the definition of "terminal" in Article 480.

Committee Action: Accepted
Resolution: SR-3633-NFPA 70-2015
Statement: Deleting "Battery" from the title aligns this definition with the definition of "terminal" in Article 480.
Battery. Two or more cells connected together electrically in series, in parallel, or a combination of both to provide the required operating voltage and current levels to form an electrical energy storage device.

Statement of Problem and Substantiation for Public Comment

The text on series and parallel connections is not needed to describe a single battery. It is more of a battery bank or system. Actually this should be moved to Art. 100 since batteries are used throughout the NEC.

Committee Statement

Committee Action: Rejected
Resolution: The text proposed to be deleted contains critical information clarifying battery connections to obtain desired voltage and/or current and is necessary to properly define a battery.
**Electrochemical Battery.**

A battery comprised of one or more rechargeable cells of the lead-acid, nickel-cadmium, or other rechargeable electrochemical types.

**Statement of Problem and Substantiation for Public Comment**

All the batteries we use are electrochemical batteries, the term electrochemical does not denote that the battery is rechargeable. Unless we want to have to write "electrochemical battery" everywhere instead of battery we should get rid of this term.

As an aside the correct way to differentiate between one use and rechargeable batteries is to use the term primary cell for one use and secondary cell for rechargeable.

**Public Comment No. 1258-NFPA 70-2015 [ Definition: Energy Storage System, Pre-engineered of Matche... ]**

**Energy Storage System, Pre-engineered of Matched Components.**

Energy storage systems that are not self-contained systems but instead are provided as separate components of pre-engineered and field-assembled using separate components supplied as a system by a singular entity, that are matched and intended to be assembled as an energy storage system at the system installation site.

Informational Note: Pre-engineered systems of matched components for field assembly as a system will generally be designed by a single entity and comprised of components that are tested and listed separately or as an assembly to safety standards relevant to the component and readily assembled on site as a system and connected on site to the electrical system.

**Statement of Problem and Substantiation for Public Comment**

The proposed change clarifies the meaning and distinction of this definition by inserting “field-assembled” in the first sentence. The remaining edits are intended to eliminate redundant language. For the “Informational Note”, the proposed change removes redundant language and in doing so puts more emphasis on the listing information, which will be useful for AHJs when checking compliance.

Public Comment No. 1116-NFPA 70-2015 [Definitions (706.2): Electrolyte... to Energy Stor...]

Definitions (706.2): Electrolyte... to Energy Stor...

Electrolyte.
The medium that provides the ion transport mechanism between the positive and negative electrodes of a cell.

Energy Storage Device.
A device for storing energy, e.g., batteries, capacitors, and kinetic energy devices.

Energy Storage System (ESS).
A device or more than one device assembled together capable of storing energy for use at a future time. ESS(s) includes but is not limited to electrochemical storage devices (e.g., batteries), flow batteries, capacitors, and kinetic energy devices (e.g., flywheels and compressed air). These systems can have ac or dc output for utilization and can include inverters and converters to change stored energy into electrical energy.

Energy storage systems where the energy storage devices such as cells, batteries, or modules and any necessary controls, ventilation, illumination, fire suppression, or alarm systems are assembled, installed, and packaged into a singular energy storage container or unit.

Informational Note: Self-contained systems will generally be manufactured by a single entity, tested and listed to safety standards relevant to the system, and readily connected on site to the electrical system and in the case of multiple systems to each other.

Energy Storage System, Pre-engineered of Matched Components.
Energy storage systems that are not self-contained systems but instead are provided as separate components of a system by a singular entity that are matched and intended to be assembled as an energy storage system at the system installation site.

Informational Note: Pre-engineered systems of matched components for field assembly as a system will generally be designed by a single entity and comprised of components that are tested and listed separately or as an assembly to safety standards relevant to the component and readily assembled on site as a system and connected on site to the electrical system.

Energy Storage System, Other.
Energy storage systems that are not self-contained or pre-engineered systems of matched components but instead are composed of individual components assembled as a system.

Informational Note: Other systems will generally be comprised of different components combined on site to create an ESS. Those components would generally be tested and listed to safety standards relevant to the application.

Statement of Problem and Substantiation for Public Comment

The term "Energy Storage Device" is used many times in this article but is not defined nor differentiated from ESS. I have provided a sample definition but another fix might be to change all uses of energy storage device to ESS.

706.5 Equipment.
Monitors and controls, switches, fuses, and breakers, power conversion systems, inverters and transformers, energy storage devices, and other components of the energy storage system shall be listed, labeled, and identified for the intended application, as a part of an energy storage system. Alternatively, prepackaged self-contained systems shall be permitted to be listed, labeled and identified for the intended application as a complete energy storage system. Only inverters listed, labeled, and identified as interactive shall be permitted on interactive systems.

Statement of Problem and Substantiation for Public Comment

Included fuses in the list of components. "As a part of an energy storage system" is not necessary and may be misconstrued. For instance, circuit breakers and fuses for application in dc portion of energy storage system must be suitable for dc application. That is they must be "listed, labeled, and identified for the intended dc application." "Identified for the application" ensures the product is appropriate for dc. This will help the installers and inspectors provide the proper equipment and components. However, for a Code compliant system for safety, the designers, installers, and inspectors still additional has to ensure equipment and components comply with the general NEC requirements such as proper voltage rating, interrupting rating, and short-circuit current ratings.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

### Public Comment No. 1725-NFPA 70-2015 [Section No. 706.7]

<table>
<thead>
<tr>
<th><strong>706.7</strong></th>
<th>Disconnecting Means.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>(A)</strong></td>
<td>ESS Disconnecting Means.</td>
</tr>
</tbody>
</table>

A disconnecting means shall be provided for all ungrounded conductors derived from an ESS. A disconnecting means shall be readily accessible and located within sight of the ESS.

- **Informational Note:** See 240.21(H) for information on the location of the overcurrent device for conductors.

- **(B)** Locking. The disconnecting means shall be lockable in accordance with 110.25.

#### (B) Remote Actuation.

Where controls to activate the disconnecting means of an ESS are not located within sight of the system, the disconnecting means shall be capable of being locked in the open position, in accordance with 110.25, and the location of the controls shall be field marked on the disconnecting means.

- **(C)** Busway.

Where a dc busway system is installed, the disconnecting means shall be permitted to be incorporated into the busway.

- **(D)** Notification.

The disconnecting means shall be legibly marked in the field. A label with the marking shall be placed in a conspicuous location near the ESS if a disconnecting means is not provided. The marking shall be of sufficient durability to withstand the environment involved and shall include the following:

1. Nominal ESS voltage
2. Maximum available fault current derived from the ESS
3. Arc flash risk assessment at the disconnecting means
4. Date the calculation was performed

- **Informational Note:** Battery equipment suppliers can provide information about short-circuit current on any particular battery model. NFPA 70E provides requirements for arc flash risk assessment.

- **(E)** Partitions and Distance.

Where energy storage device input and output terminals are more than 1.5 m (5 ft) from connected equipment, or where the circuits from these terminals pass through a wall or partition, the installation shall comply with the following:

1. A disconnecting means and overcurrent protection shall be provided at the energy storage device end of the circuit. Fused disconnecting means or circuit breakers shall be permitted to be used.
2. Where fused disconnecting means are used, the line terminals of the disconnecting means shall be connected toward the energy storage device terminals.
3. Overcurrent devices or disconnecting means shall not be installed in energy storage device enclosures where explosive atmospheres can exist.
4. A second disconnecting means located at the connected equipment shall be installed where the disconnecting means required by 706.7(E) (1) is not within sight of the connected equipment.
5. Where the energy storage device disconnecting means is not within sight of the ESS disconnecting means, placards or directories shall be installed at the locations of all disconnecting means indicating the location of all disconnecting means.

---

**Statement of Problem and Substantiation for Public Comment**

A requirement for the disconnecting means to be lockable is added as noted in the Committee Statement. A new subclause 706.7(B) is proposed to be added as follows, and the existing subclauses thereafter to be assigned a new letter.

- **(B)** Locking. The disconnecting means shall be lockable in accordance with 110.25.

**Related Item**

</tbody>
</table>
Public Comment No. 1101-NFPA 70-2015 [Section No. 706.7(B)]

(B) Remote Actuation Location.
Where controls to activate the disconnecting means of an ESS are not located within sight of the system, the disconnecting means shall be capable of being locked in the open position, in accordance with 110.25, and the location of the controls shall be field marked on the disconnecting means.

Statement of Problem and Substantiation for Public Comment

This section deals with the location of the controls that control the disconnection means not being within line of sight of the ESS, not remote actuation of something as the heading suggests. "Actuation" was changed to "Location" to correct this.

City: 
State: 
Zip: 
Submittal Date: Wed Sep 23 17:47:57 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: This section addresses actuation, not location of the disconnecting means.
Public Comment No. 1102-NFPA 70-2015 [Section No. 706.7(D)]

(D) Notification.

The disconnecting means shall be legibly marked in the field. A label with the marking shall be placed in a conspicuous location near the ESS if a disconnecting means is not provided. The marking shall be of sufficient durability to withstand the environment involved, meet the requirements of 110.21(B) and shall include the following:

1. Nominal ESS voltage
2. Maximum available fault current derived from the ESS
3. Arc flash risk assessment at the disconnecting means. Date the calculation was performed hazard warning meeting the requirements of 110.16.

Informational Note: Battery equipment suppliers can provide information about short-circuit current on any particular battery model. NFPA 70E provides requirements for arc flash risk assessment.

Statement of Problem and Substantiation for Public Comment

Changed the marking requirements to point to 110.21(B) since an arc flash warning is a hazard marking and this article provides more information on markings. Changed (3) to point to the arc flash hazard warning requirements of 110.16. Removed requirement for calculation date since that requirement is going to be covered by NFPA 70E. No reason to double dip on the requirements.

Resolution: SR-3642-NFPA 70-2015
Statement: The second sentence was deleted as there is no exception in 706.7 (A) to allow the disconnect to be omitted. "Fault current" was changed to "short circuit current" for proper terminology. Arc flash risk assessment was expanded to include marking requirements in 110.16.
Public Comment No. 1137-NFPA 70-2015 [Section No. 706.7(D)]

(D) Notification.
The disconnecting means shall be legibly marked in the field. A label with the marking shall be placed in a conspicuous location near the ESS if a disconnecting means is not provided. The marking shall be of sufficient durability to withstand the environment involved and shall include the following:

1. Nominal ESS voltage
2. Maximum available fault current, short-circuit current, derived from the ESS
3. Arc flash risk assessment at the disconnecting means
4. Date the calculation was performed

Informational Note: Battery equipment suppliers can provide information about short-circuit current on any particular battery model. NFPA 70E provides requirements for arc flash risk assessment.

Statement of Problem and Substantiation for Public Comment

The language should state short-circuit current, not fault current.

Note: Terraview is indicating that the informational note has been changed (it is underlined) however no intentional changes were made to the note in this comment.

Submittal Date: Wed Sep 23 22:02:20 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-3642-NFPA 70-2015
Statement: The second sentence was deleted as there is no exception in 706.7 (A) to allow the disconnect to be omitted. “Fault current” was changed to “short circuit current” for proper terminology. Arc flash risk assessment was expanded to include marking requirements in 110.16.
Public Comment No. 1138-NFPA 70-2015 [Section No. 706.7(D)]

(D) Notification.
The disconnecting means shall be legibly marked in the field. A label with the marking shall be placed in a conspicuous location near the ESS if a disconnecting means is not provided. The marking shall be of sufficient durability to withstand the environment involved and shall include the following:

1. Nominal ESS voltage
2. Maximum available fault current derived from the ESS
3. Arc flash risk assessment at the disconnecting means
4. Date the calculation was performed

Informational Note: Battery equipment suppliers can provide information about short-circuit current on any particular battery model. NFPA 70E provides requirements for arc flash risk assessment.

Statement of Problem and Substantiation for Public Comment

The assessment of arc fault risk is better addressed in NFPA 70E, and marking each disconnecting means with a label advising an installer to perform a risk assessment does not add value. Marking the specific calculated arc flash exposure could be more relevant, but this is already addressed in 110.16. 110.16 does not specifically apply to dwelling units, however the operating voltage of most residential storage systems will be less than 100v; which is not addressed in NFPA 70E (the minimum hazard voltage in 70E Table 130.7(C)(15)(B) is 100-250VDC); therefore this requirement adds little to no increase in installer safety yet will cause confusion and conflicting interpretations, with no standards-based guidance on performing the calculation.

Note: Terraview is indicating that the informational note has been changed (it is underlined) however no intentional changes were made to the note in this comment.

Committee Statement

Committee Action: Rejected
Resolution: The submitter has not provided adequate substantiation to warrant removal of list item (3).
Public Comment No. 1184-NFPA 70-2015 [Section No. 706.7(D)]

(D) Notification.

The disconnecting means shall be legibly marked in the field. A label with the marking shall be placed in a conspicuous location near the ESS if a disconnecting means is not provided. The marking shall be of sufficient durability to withstand the environment involved and shall include the following:

1. Nominal ESS voltage
2. Maximum available fault current derived from the ESS
3. Arc flash risk assessment at hazard value at the disconnecting means
4. Date the calculation was performed

Informational Note: Battery equipment suppliers can provide information about short-circuit current on any particular battery model. NFPA 70E provides requirements for arc flash risk assessment.

Statement of Problem and Substantiation for Public Comment

It is not clear what is wanted in 706.7(D)(3), "arc flash risk assessment." As hazard identification and risk assessment are two separate things in NFPA 70E, I assume that the intent is to identify the arc flash value and/or the PPE at the disconnecting means.

Statement: The second sentence was deleted as there is no exception in 706.7 (A) to allow the disconnect to be omitted. "Fault current" was changed to "short circuit current" for proper terminology. Arc flash risk assessment was expanded to include marking requirements in 110.16.
Public Comment No. 1596-NFPA 70-2015 [Section No. 706.7(D)]

(D) Notification.

The disconnecting means shall be legibly marked in the field. A label with the marking shall be placed in a conspicuous location near the ESS if a disconnecting means is not provided. The marking shall be of sufficient durability to withstand the environment involved and shall include the following:

1. Nominal ESS voltage
2. Maximum available fault short-circuit current derived from the ESS
3. Arc flash risk assessment at the disconnecting means
4. Date the calculation was performed

Informational Note: Battery equipment suppliers can provide information about short-circuit current on any particular battery model. NFPA 70E provides requirements for arc flash risk assessment.

Statement of Problem and Substantiation for Public Comment

706.7(A) requires a disconnect within sight of the ESS, so the second sentence of the FR is not necessary. Maximum available short-circuit current is a more suitable term for this section than maximum available fault current.

Partitions and Distance.

Where energy storage device input and output terminals are more than 1.5 m (5 ft) from connected equipment, or where the circuits from these terminals pass through a wall or partition, the installation shall comply with the following:

1. A disconnecting means and overcurrent protection shall be provided at the energy storage device end of the circuit. Fused disconnecting means or circuit breakers shall be permitted to be used.

2. Where fused disconnecting means are used, the line terminals of the disconnecting means shall be connected toward the energy storage device terminals.

3. Overcurrent devices or disconnecting means shall not be installed in energy storage device enclosures where explosive atmospheres can exist.

4. A second disconnecting means located at the connected equipment shall be installed where the disconnecting means required by 706.7(E) (1) is not within sight of the connected equipment.

5. Where the energy storage device disconnecting means is not within sight of the ESS disconnecting means, placards or directories shall be installed at the locations of all disconnecting means indicating the location of all disconnecting means.

Statement of Problem and Substantiation for Public Comment

This section needs to be harmonized with 706.21. Right now they are fighting over the same turf. Since this section is supposed to relate to disconnecting means the requirements for overcurrent devices should be moved to 706.21.

Resolution: SR-3644-NFPA 70-2015
Statement:
List items are editorially revised for clarity.

References to overcurrent protection and overcurrent devices are deleted as this section addresses only disconnecting means.

New list item (4) is modified for clarity to reference hazardous locations.

New informational notes are added to aid the Code user.

Additional editorial corrections are made for clarity.
Partitions and Distance.

Where energy storage device input and output terminals are more than 1.5 m (5 ft) from connected equipment, or where the circuits from these terminals pass through a wall or partition, the installation shall comply with the following:

1. A disconnecting means and overcurrent protection shall be provided at the energy storage device end of the circuit. Fused disconnecting means or circuit breakers shall be permitted to be used.

2. A second disconnecting means located at the connected equipment shall be installed where the disconnecting means required by 706.7(E)(1) is not within sight of the connected equipment.

Informational Note No. 1: For remote disconnect controls in information technology equipment rooms, see 645.10

Informational Note No. 2: For overcurrent protection of batteries, see 240.21(H)

1. Where fused disconnecting means are used, the line terminals of the disconnecting means shall be connected toward the energy storage device terminals.

2. Overcurrent devices or disconnecting means shall not be installed in energy storage device enclosures where explosive atmospheres can exist.

3. A second disconnecting means located at the connected equipment shall be installed where the disconnecting means required by 706.7(E)(1) is not within sight of the connected equipment.

4. Where the energy storage device disconnecting means is not within sight of the ESS disconnecting means, placards or directories shall be installed at the locations of all disconnecting means indicating the location of all disconnecting means.

Statement of Problem and Substantiation for Public Comment

This public comment recommends the following:
1. Editorial change: Move Item #4 to Item #2 for a more logical sequence.
2. Add two new informational notes regarding the location of the disconnecting means
   a. When an ESS is for information technology equipment, such as an uninterruptible power supply (UPS) system, the reader should follow the rules in Article 645 for remote disconnecting means.
   b. 240.21(H) says that overcurrent protection shall be permitted to be installed "as close as practicable" to the storage battery terminals. Use of this terminology was deliberate. Due to physical obstructions in a room, it may not always be possible - or at least practicable - to place the OCPD within 1.5m (5 ft) of the battery terminals. The goal is to keep the unprotected dc cables as short as reasonably possible.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-3644-NFPA 70-2015
Statement: List items are editorially revised for clarity.

References to overcurrent protection and overcurrent devices are deleted as this section addresses only disconnecting means.

New list item (4) is modified for clarity to reference hazardous locations.

New informational notes are added to aid the Code user.
Additional editorial corrections are made for clarity.
Partitions and Distance.

Where energy storage device input and output terminals are more than 1.5 m (5 ft) from connected equipment, or where the circuits from these terminals pass through a wall or partition, the installation shall comply with the following:

1. A disconnecting means and overcurrent protection shall be provided at the energy storage device end of the circuit. Fused disconnecting means or circuit breakers shall be permitted to be used.
2. Where fused disconnecting means are used, the line terminals of the disconnecting means shall be connected toward the energy storage device terminals.
3. Overcurrent devices or disconnecting means shall not be installed in energy storage device enclosures where explosive atmospheres can exist.
4. A second disconnecting means located at the connected equipment shall be installed where the disconnecting means required by 706.7(E) (1) is not within sight of the connected equipment.
5. Where the energy storage device disconnecting means is not within sight of the ESS disconnecting means, placards or directories shall be installed at the locations of all disconnecting means indicating the location of all disconnecting means.

Statement of Problem and Substantiation for Public Comment

The term "energy storage device" is ambiguous and could be interpreted to apply to individual components of a pre-engineered ESS listed for field assembly. The listing for the field assembly will address all requirements for the interconnection of separate components within the pre-engineered ESS, including disconnecting means. It should be clear to installers and AHJs in this case that no additional disconnects are required. The proposed exception addresses this scenario specifically. The replacement of "the following" with "(1) through (5)" in the intro paragraph better facilitates the insertion of the exception language.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

An inverter in an interactive energy storage system shall automatically de-energize its output to the connected electrical production and distribution network upon loss of voltage in that system and shall remain in that state until the electrical production and distribution network voltage has been restored. A normally interactive energy storage system shall be permitted to operate as a stand-alone system to supply loads that have been disconnected from electrical production and distribution network sources. ESS with a utility interactive inverter shall comply with the requirements of 705.40 upon loss of primary source.

Statement of Problem and Substantiation for Public Comment

This requirement does not differ from those specified in 705.40 for any utility interactive power source. The proposed revision references 705.40 directly instead of rephrasing language.

Committee Statement

| Committee Action: Rejected but see related SR |
| Resolution: SR-3645-NFPA 70-2015 |
| Statement: This revision references 705.40 directly instead of rephrasing language. |
Loss of Interactive System Power.

An inverter in an interactive energy storage system shall automatically de-energize its output to the connected electrical production and distribution network upon loss of voltage in that system and shall remain in that state until the electrical production and distribution network voltage has been restored. A normally interactive energy storage system shall be permitted to operate as a stand-alone system to supply loads that have been disconnected from electrical production and distribution network sources. *This requirement is in conflict with low-voltage ride-through.*

**Statement of Problem and Substantiation for Public Comment**

Some systems require low-voltage ride-through which seems to be in conflict with this requirement at least short-term.

City:  
State:  
Zip:  
Submittal Date: Wed Jul 29 06:55:00 EDT 2015

**Committee Statement**

Committee Action: Rejected  
Resolution: The submitter provides no proposed revisions. The comment does not comply with Section 4.4.4.4 of the NFPA Regulations Governing The Development of NFPA Standards include proposed text in the Public Comment including the wording to be added, revised, or deleted.
Public Comment No. 1189-NFPA 70-2015 [Section No. 706.10(A)]

(A) Ventilation.
Provisions appropriate to the energy storage technology shall be made for sufficient diffusion and ventilation of any possible gases from the storage device, if present, to prevent the accumulation of an explosive or poisonous mixture. A pre-engineered or self-contained ESS shall be permitted to provide ventilation in accordance with the manufacturer’s recommendations and listing for the system.

Informational Note No. 1: See NFPA 1-2015, Fire Code, Chapter 52, for ventilation considerations and fire protection, for specific battery chemistries.

Informational Note No. 2: Some storage technologies do not require ventilation.

Informational Note No. 4: Fire protection considerations are addressed in NFPA 1-2015, Fire Code.

Statement of Problem and Substantiation for Public Comment

Ventilation is required not only for explosive gasses vented by some batteries (e.g., hydrogen). Poisonous gas is also a possibility (e.g., hydrogen sulfide). This PC adds the words “or poisonous”

This PC also revises Informational Note No. 1 to include the words “and fire protection” because Chapter 52 of NFPA 1 addresses the ventilation design and controls necessary for fire protection

This PC also deletes Informational Note No. 4 because it duplicates Informational Note #1.

Submitter Information Verification

Submitter Full Name: STEPHEN MCCLUER
Organization: STEVE MCCLUER LLC
Street Address:
City:
State:
Zip:
Submittal Date: Thu Sep 24 11:27:08 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The panel does not accept “poisonous” as it is outside the scope of the NEC. Both Informational Notes are retained. Informational Note 1 references Chapter 52 of NFPA 1 and Informational Note 4 references NFPA 1 in its entirety.
706.10(D) Top Terminal Batteries. Where top terminal batteries are installed on tiered racks, working space in accordance with the battery manufacturer’s instructions shall be provided between the highest point on a cell and the row or ceiling above that point. Informational Note: Battery manufacturer’s installation instructions typically define how much top working space is necessary for a particular battery model.

Statement of Problem and Substantiation for Public Comment

It seems to be the intent of the new Article 706, Energy Storage Systems, to incorporate all of the requirements from Article 480, Storage Batteries. Section 480.9(D) was not carried over. Because the greatest risk of electrocution or arc flash occurs when a worker inadvertently comes in contact with battery terminals, the amount of clearance above the terminals is crucial. This is especially important for top-terminal batteries that are installed inside of cabinets.

Submitter Full Name: STEPHEN MCCLUER
Organization: STEVE MCCLUER LLC
Street Address:
City:
State:
Zip:
Submittal Date: Thu Sep 24 11:37:55 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: This proposed text presently exists in 480.9(D) which applies generally as per Section 90.3.
Public Comment No. 1277-NFPA 70-2015 [Section No. 706.10(D)]

(D) Egress.
A. Where an ESS includes a room dedicated solely for the containment of electrochemical batteries, personnel door(s) intended for entrance to and egress from rooms designated as ESS rooms, the battery room, shall open in the direction of egress and shall be equipped with listed panic hardware.

Statement of Problem and Substantiation for Public Comment

The draft requirement copies the egress requirement found in 480.9(E) for designated battery rooms, but applies the language to "ESS rooms." As ESS is a broad term with multiple categories, this requirement could be interpreted to apply to rooms containing listed ESS components and assemblies that already address containment of the storage devices, and which are suitable for installation in multi-purpose rooms. The revision clarifies that the intent of the egress requirement is for dedicated and designated battery rooms.

Committee Statement

Committee Action: Rejected
Resolution: Rooms designated for ESS may present hazards similar to those presented by batteries where quick and immediate egress is required.
Public Comment No. 1191-NFPA 70-2015 [New Section after 706.10(E)]

(F) Piping In Battery Rooms.
Gas piping shall not be permitted to dedicated battery rooms.

Statement of Problem and Substantiation for Public Comment
It seems to be the intent of the new Article 706, Energy Storage Systems to incorporate all of the requirements from Article 480, Storage Batteries. Section 480.9(F) was not carried over. This PC creates a new paragraph. The logical place to put this section is following 706.10(E)(2), Illumination. Renumber any subsequent sub-paragraphs.

Committee Statement
Committee Action: Rejected
Resolution: Section 706.10 covers Energy Storage System Locations. The proposed requirement is not relevant to this section. If a room is dedicated for batteries as part of an ESS, then Article 480 applies.
### Public Comment No. 1139-NFPA 70-2015 [Section No. 706.20(A)]

#### Calculation of Maximum Circuit Current

The maximum current for the specific circuit shall be calculated in accordance with 706.20(A)(1) through (A)(5).

1. **Nameplate Rated Circuit Current.**
   - The nameplate(s) rated circuit current shall be the rated current indicated on the ESS nameplate(s) or system listing for pre-engineered or self-contained systems of matched components intended for field assembly as a system.

2. **Inverter Output Circuit Current.**
   - The maximum current shall be the inverter continuous output current rating.

3. **Inverter Input Circuit Current.**
   - The maximum current shall be the continuous inverter input current rating when the inverter is producing rated power at the lowest input voltage.

4. **Inverter Utilization Output Circuit Current.**
   - The maximum current shall be the continuous inverter output current rating when the inverter is producing rated power at the lowest input voltage.

5. **DC to DC Converter Output Current.**
   - The maximum current shall be the dc-to-dc converter continuous output current rating.

---

#### Statement of Problem and Substantiation for Public Comment

The title for this requirement was inadvertently deleted or left off.

#### Committee Statement

- **Committee Action:** Rejected but see related SR
- **Resolution:** SR-3646-NFPA 70-2015
- **Statement:** A first level subdivision title is added as required by the NEC Style Manual.
Public Comment No. 1715-NFPA 70-2015 [Section No. 706.20(A)]

(A) Maximum Rated Current for a Specific Circuit
The maximum current for the specific circuit shall be calculated in accordance with 706.20(A)(1) through (A)(5).

(1) Nameplate Rated Circuit Current.
The nameplate(s) rated circuit current shall be the rated current indicated on the ESS nameplate(s) or system listing for pre-engineered or self-contained systems of matched components intended for field assembly as a system.

(2) Inverter Output Circuit Current.
The maximum current shall be the inverter continuous output current rating.

(3) Inverter Input Circuit Current.
The maximum current shall be the continuous inverter input current rating when the inverter is producing rated power at the lowest input voltage.

(4) Inverter Utilization Output Circuit Current.
The maximum current shall be the continuous inverter output current rating when the inverter is producing rated power at the lowest input voltage.

(5) DC to DC Converter Output Current.
The maximum current shall be the dc-to-dc converter continuous output current rating.

Statement of Problem and Substantiation for Public Comment
A title is needed in 706.20(A) as pointed out in Linda Little’s affirmative ballot comments.

City:
State:
Zip:
Submittal Date: Fri Sep 25 17:35:29 EDT 2015

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-3646-NFPA 70-2015
Statement: A first level subdivision title is added as required by the NEC Style Manual.
(3) Inverter Input Circuit Current.

The (1) For applications in which the full load reserve time is rated for longer than three hours, the maximum current shall be the continuous inverter input current rating when the inverter is producing rated power at the lowest input voltage.

(2) For applications in which the full load reserve time is rated for less than three hours, the maximum current shall be 80 percent of the inverter input current rating when the inverter is producing rated power at the lowest input voltage.

Statement of Problem and Substantiation for Public Comment

Article 100 defines "continuous load" as "a load where the maximum current is expected to continue for 3 hours or more." Per Ohm’s Law, current increases proportionately to a decrease in voltage. In a battery system, voltage continues to drop from the time it starts discharging. The rate of voltage drop (and corresponding current rise) increases rapidly as the battery nears end voltage. In photovoltaic, wind system, and some telecommunications applications, run times in excess of three hours are expected. In uninterrupted power supply (UPS) applications, run times of less than one hour are the rule, with most being between 5 to 15 minutes. Rating the input current from a battery to a UPS inverter based upon the maximum current during the final minute of discharge will result in significantly over-sizing conductors and overcurrent protective devices. The present language of 706.20(A)(3) fails to take into account multiple variables, which can include voltage, time, temperature, and current.

Submittal Date: Thu Sep 24 11:43:15 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The submitter did not provide technical substantiation which supports the 80% rating for all battery technologies and derating may not be applicable to all inverter technologies.
706.21 Overcurrent Protection.

(A) Circuits and Equipment.

Energy storage circuit conductors shall be protected in accordance with the requirements of Article 240. Protection devices for ESS circuits shall be in accordance with the requirements of 706.11(B) through (F). Circuits shall be protected at the source from overcurrent.

(B) Overcurrent Device Ampere Ratings.

Overcurrent protective devices, where required, shall be rated in accordance with Article 240 and the rating provided on systems serving the ESS and shall be not less than 125 percent of the maximum currents calculated in 706.10(A).

(C) Direct Current Rating.

Overcurrent protective devices, either fuses or circuit breakers, used in any dc portion of an ESS shall be listed and shall have the appropriate voltage, current, and interrupting ratings.

(D) Prime Movers.

Overcurrent protection shall not be required for conductors from an ESS with a nominal voltage of 50 volts or less if these conductors provide power for starting, ignition, or control of prime movers. Section 300.3 shall not apply to these conductors.

(E) Current Limiting.

A listed, current-limiting, overcurrent device shall be installed in each dc output circuit adjacent to the ESS.

(F) Fuses.

Means shall be provided to disconnect any fuses associated with ESS equipment and components when the fuse is energized from both directions and is accessible to other than qualified persons. Switches, pullouts, or similar devices that are rated for the application shall be permitted to serve as a means to disconnect fuses from all sources of supply.

(G) Location

Where energy storage device input and output terminals are more than 1.5 m (5 ft) from connected equipment, or where the circuits from these terminals pass through a wall or partition overcurrent protection shall be provided at the ESS.

Statement of Problem and Substantiation for Public Comment

Moved text here from 706.7 to better harmonize the two sections. Section 706.7 should be limited to disconnecting means and this section to OCPD.

Statement: This revision editorially revises first level subdivisions (A)(B), and (C). First level subdivision (D) is deleted as it is presently covered in Article 480. First level subdivision (E) (now (D)) is revised for clarity and a new exception is added to address situations where current limiting overcurrent protection is provided for the dc output circuits of a listed and labeled ESS. A new first level subdivision (F) is added to clarify the location of the required OCPD where conductors pass through a wall or partition.
Sections 706.21(A), 706.21(B), 706.21(C)

(A) Circuits and Equipment.
Energy storage circuit conductors shall be protected in accordance with the requirements of Article 240. Protection devices for ESS circuits shall be in accordance with the requirements of 706.21(B), through (F). Circuits shall be protected at the source from overcurrent.

(B) Overcurrent Device Ampere Ratings.
Overcurrent protective devices, where required, shall be rated in accordance with Article 240 and the rating provided on systems serving the ESS and shall be not less than 125 percent of the maximum currents calculated in 706.10(A).

(C) Direct Current Rating.
Overcurrent protective devices, either fuses or circuit breakers, used in any dc portion of an ESS shall be listed, labeled, and shall have identified with the appropriate voltage, current, and interrupting ratings.

Statement of Problem and Substantiation for Public Comment

The reference to 706.11 appeared to be a typo.

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-3648-NFPA 70-2015
Statement: This revision editorially revises first level subdivisions (A)(B), and (C). First level subdivision (D) is deleted as it is presently covered in Article 480. First level subdivision (E) (now (D)) is revised for clarity and a new exception is added to address situations where current limiting overcurrent protection is provided for the dc output circuits of a listed and labeled ESS. A new first level subdivision (F) is added to clarify the location of the required OCPD where conductors pass through a wall or partition.
(C) Direct Current Rating.
Overcurrent protective devices, either fuses or circuit breakers, used in any dc portion of an ESS shall be listed and labeled for dc and shall have the appropriate voltage, current ampere, and interrupting ratings for the application.

Statement of Problem and Substantiation for Public Comment

If a product is labeled it makes it easier for the installer and AHJ to ensure a product is listed for dc. Ampere rating as used in 240.6 is the proper term rather than current rating. It is important the product has a proper voltage rating, ampere rating, and interrupting rating for the specific application.

A new first level subdivision (F) is added to clarify the location of the required OCPD where conductors pass through a wall or partition.
Public Comment No. 1280-NFPA 70-2015 [Section No. 706.21(E)]

(E) Current Limiting.
A listed, current-limiting, overcurrent device shall be installed in each dc output circuit adjacent to the ESS.

*Exception: DC output circuits between components of a listed, pre-engineered ESS shall be permitted without additional overcurrent devices where in accordance with the manufacturer's listing.*

Statement of Problem and Substantiation for Public Comment

The requirement could be interpreted to apply to circuits that interconnect components within a pre-engineered ESS listed for field assembly. The listing for the field assembly will address all requirements for the interconnection of the separate components, including overcurrent protection. It should therefore be clear to installers and AHJs in this case that no additional overcurrent protection components are required. The proposed exception addresses this scenario specifically.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

Wiring and equipment supplied from ESS(s) and system components shall be subject to the applicable provisions of this Code applying to wiring and equipment operating at the same voltage, unless otherwise permitted by this article.

Statement of Problem and Substantiation for Public Comment
The requirement is a bit confusing and does not add any new requirements, and therefore is "teaching the code." The proposed deletion is for brevity and clarity.

Committee Statement
Committee Action: Accepted
Resolution: SR-3649-NFPA 70-2015
Statement: Section 706.22 is deleted because it did not contain a requirement, only references to other areas of the NEC.

Systems using utility interactive inverters to control energy storage state-of-charge by diverting excess power into the utility system shall comply with 706.23(B)(3)(a) and (B)(3)(b).

(a) These systems shall not be required to comply with 706.23(B)(2).

(b) These systems shall have a second, independent means of controlling the ESS charging process for use when the electrical production and distribution network is not present or when the primary charge controller fails or is disabled.

Statement of Problem and Substantiation for Public Comment

Harmonize this with the other changes to remove the "utility" limitation from interactive inverters.

Submittal Date: Wed Sep 23 20:24:17 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The submitter did not provide adequate substantiation to remove "utility" along with the other suggested changes.

Systems using utility-interactive inverters to control energy storage state-of-charge by diverting excess power into the utility system shall comply with 706.23(B)(3) (a) and (B)(3)(b).

(a) These systems shall not be required to comply with 706.23(B)(2).

(b) These systems shall have a second, independent means of controlling the ESS charging process for use when the utility is not present or when the primary charge controller fails or is disabled. *My understanding of utility-interactive inverters is that charging the storage system is not possible when the utility is not present. Also, this appears to be asking for redundant charge controllers. This seems burdensome. Could the intent be accomplished with a fail-safe controller?*

Statement of Problem and Substantiation for Public Comment

Redundant charge controllers seems like a burdensome requirement.

Committee Statement

Committee Action: Rejected
Resolution: The submitter provides no proposed revisions. The comment does not comply with Section 4.4.4.4 of the NFPA Regulations Governing The Development of NFPA Standards include proposed text in the Public Comment including the wording to be added, revised, or deleted.
Public Comment No. 1140-NFPA 70-2015 [Section No. 706.23(C)]

(C) Charge controllers and DC, dc-to-dc, converters.

When charge controllers and other dc-to-dc power converters that increase or decrease the output current or output voltage with respect to the input current or input voltage are installed the requirements shall comply with 706.23(C)(1) and (C)(2).

1. The ampacity of the conductors in output circuits shall be based on the maximum rated continuous output current of the charge controller or converter for the selected output voltage range, and

2. The voltage rating of the output circuits shall be based on the maximum voltage output of the charge controller or converter for the selected output voltage range.

Statement of Problem and Substantiation for Public Comment

Revised for clarity, and the term DC converters was replaced with dc-to-dc converters to harmonize with other articles and sections of the code.

Submittal Date: Wed Sep 23 22:12:44 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-3650-NFPA 70-2015
Statement: The requirement is split into list items for clarity and “dc power converters” is changed to “DC-DC power converters”.
(C) Charge controllers and DC converters.

When charge controllers and other dc power converters that increase or decrease the output current or output voltage with respect to the input current or input voltage are installed, they shall comply with the following:

1) The ampacity of the conductors in output circuits shall be based on the maximum rated continuous output current of the charge controller or converter for the selected output voltage range, and

2) The voltage rating of the output circuits shall be based on the maximum voltage output of the charge controller or converter for the selected output voltage range.

Statement of Problem and Substantiation for Public Comment

This section is reformatted and revised for clarity as noted in Linda Little's affirmative comment. The proposed wording is as follows:

(C) Charge controllers and DC converters. Charge controllers and other dc power converters that increase or decrease the output current or output voltage with respect to the input current or input voltage shall comply with the following:

1) The ampacity of the conductors in output circuits shall be based on the maximum rated continuous output current of the charge controller or converter for the selected output voltage range, and

2) The voltage rating of the output circuits shall be based on the maximum voltage output of the charge controller or converter for the selected output voltage range.

Statement: The requirement is split into list items for clarity and “dc power converters” is changed to “DC-DC power converters”.

National Fire Protection Association Report http://submittals.nfpa.org/TerraViewWeb/ContentFetcher?commentPara...
Installation of Batteries.

Storage batteries associated with an ESS shall be installed in accordance with the provisions this article.

(A) Dwelling Units.

ESSs. An ESS for dwellings shall be configured so as to operate at a voltage of 100 volts or less. Dwelling units shall not exceed 100 volts between conductors or to ground.

Exception: Where live parts are not accessible during routine ESS maintenance, an ESS voltage greater than, exceeding, 100 volts shall be permitted.

(B) Storage System Nonconductive Cases and Conductive Racks.

Flooded, vented lead-acid batteries where operating at more than, exceeding, 100 volts, shall, nominal, between terminals shall, not use conductive cases or shall not be installed in conductive cases. Conductive racks used to support nonconductive cases shall be permitted where no rack material is located within 150 mm (6 in.) of the tops of the nonconductive cases.

Exception: This requirement shall not apply to any type of valve-regulated lead-acid (VRLA) battery or other types of sealed batteries that may require steel cases for proper operation.

Note: Parts VI and VII of Article 250 address exposed metal parts.

(C) Disconnection of Series Battery Circuits.

Battery circuits subject to field servicing, where operating at more than, exceeding, 100 volts between conductors or to ground, shall have provisions to disconnect the series-connected strings into segments of, not exceeding, 100 volts or less, for maintenance by qualified persons. Non–load-break bolted or plug-in disconnects shall be permitted.

(D) Storage System Maintenance Disconnecting Means.

ESS greater than, exceeding, 100 volts shall, between conductors or to ground, have a disconnecting means, accessible only to qualified persons, that disconnects the grounded circuit conductor(s) in the electrical storage system for maintenance. This disconnecting means shall not disconnect the grounded circuit conductor(s) for the remainder of any other electrical system. A non–load-break-rated switch shall be permitted to be used as a disconnecting means.

(E) Storage Systems of More Than, Exceeding, 100 Volts.

On electrochemical ESS operating at more than, exceeding, 100 volts between conductors or to ground, the system shall be permitted to operate with ungrounded conductors, provided a ground-fault detector and indicator is installed to monitor for ground faults within the storage system.

Statement of Problem and Substantiation for Public Comment

Text did not use recommended limit expressions from the NEC style manual.

Submittal Date: Fri Sep 25 13:37:43 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-3651-NFPA 70-2015
Statement: The parent text to 706.30 has been removed for clarity.

This revision editorially revises first level subdivision (A) and the associated exception.
First level subdivision (B) is deleted as this requirement presently exists in Article 480.

First level subdivisions (C), (D), and (E) (now (B), (C), and (D)) are editorially revised.

The 100 volt threshold in (C) (now (D)) is modified to address current practice.
Public Comment No. 1283-NFPA 70-2015 [Section No. 706.30(A)]

(A) Dwelling Units.

ESSs for dwellings shall have the batteries configured so as to operate at a voltage of 100 volts or less.

Exception: Where live parts are not accessible during routine ESS maintenance, an ESS with batteries voltage greater than 100 volts shall be permitted.

Statement of Problem and Substantiation for Public Comment

ESS by itself is a broad term, and the requirement historically applies to the energy storage (battery) circuits. An ESS with dc/dc converters or inverters may have voltages exceeding 100V. These should not have accessible live parts in any case, but it is important to make this distinction to reduce confusion for AHJs.

Submittal Date: Fri Sep 25 13:50:11 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The panel does not agree that the facility services for large multi-unit dwellings are normally secured and accessed only by qualified service personnel.
(B) Storage System Nonconductive Cases and Conductive Racks.

Flooded, vented lead-acid batteries where operating at more than 100 volts shall not use conductive cases or shall not be installed in conductive cases. Conductive racks used to support nonconductive cases shall be permitted where no rack material is located within 150 mm (6 in.) of the tops of the nonconductive cases.

Exception: This requirement shall not apply to any type of valve-regulated lead-acid (VRLA) battery or other types of sealed batteries that may require steel cases for proper operation.

Note: Parts VI and VII of Article 250 address exposed metal parts.

Statement of Problem and Substantiation for Public Comment

The exception is technically not required since (B) only applies to vented batteries. Maybe it is here to make it exceedingly clear the it does not apply to sealed batteries but it is redundant.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-3651-NFPA 70-2015
Statement: The parent text to 706.30 has been removed for clarity.

This revision editorially revises first level subdivision (A) and the associated exception.

First level subdivision (B) is deleted as this requirement presently exists in Article 480.

First level subdivisions (C), (D), and (E) (now (B), (C), and (D)) are editorially revised.

The 100 volt threshold in (C) (now (D)) is modified to address current practice.
Public Comment No. 1284-NFPA 70-2015 [Section No. 706.30(D)]

(D) Storage System Maintenance Disconnecting Means.

ESS greater than Electrochemical ESS with both grounded conductors and batteries configured so as to operate at more than 100 volts shall have a disconnecting means, accessible only to qualified persons, that disconnects the grounded circuit conductor(s) in the electrical storage system for maintenance. This disconnecting means shall not disconnect the grounded circuit conductor(s) for the remainder of any other electrical system(s). A non-load-break-rated switch shall be permitted to be used as a disconnecting means.

Statement of Problem and Substantiation for Public Comment

ESS by itself is a broad term and could include converted dc and ac circuits, while the requirement historically applies to the energy storage (battery) circuits. The proposed change clarifies the criteria. The condition "with grounded conductors" is also added to clarify that additional disconnecting means is not required if the battery circuits are ungrounded.

Committee Statement

Committee Action: Rejected
Resolution: These revisions are not necessary as 706.30 applies only to the installation of batteries.
Public Comment No. 1512-NFPA 70-2015 [Section No. 706.30(D)]

(D) Storage System Maintenance Disconnecting Means.

ESS greater than 100 volts shall have a disconnecting means, accessible only to qualified persons, that disconnects the ungrounded and grounded circuit conductor(s) in the electrical storage system for maintenance. This disconnecting means shall not disconnect the grounded circuit conductor(s) for the remainder of any other electrical system. A non-load-break-rated switch shall be permitted to be used as a disconnecting means.

Statement of Problem and Substantiation for Public Comment

Maybe I am missing something here but I'm not sure what the purpose is to have a disconnecting means that only disconnects the grounded circuit conductor. I would think we would want to disconnect all the current carrying conductors to perform maintenance while insuring that it does not effect the grounding of other system conductors.

First level subdivision (B) is deleted as this requirement presently exists in Article 480.
First level subdivisions (C), (D), and (E) (now (B), (C), and (D)) are editorially revised.
The 100 volt threshold in (C) (now (D)) is modified to address current practice.
(E) Storage Systems of More Than 100 Volts.

On electrochemical ESS operating at more than 100 volts, the system battery circuits shall be permitted to operate with ungrounded conductors, provided a ground-fault detector and indicator is installed to monitor for ground faults within the storage system.

Statement of Problem and Substantiation for Public Comment

690.71(G), which this requirement replaces, has permitted systems above this voltage threshold to operate with ungrounded conductors, provided ground-fault detection and indication is installed. This option has been provided due to the low level of leakage current common with some electrochemical batteries which if not operated as ungrounded and isolated might lead to unintended failures. In addition, the Handbook under 250.167 DC ground fault protection indicates that some DC applications cannot use a grounded system. While the Handbook commentary is informative and not Code, it provides real-world examples. Ultimately, the product Listing should prevail. This revision is to clarify that this permissive operation applies only to the battery circuits.

Statement: The parent text to 706.30 has been removed for clarity.

The revision editorially revises first level subdivision (A) and the associated exception.

First level subdivision (B) is deleted as this requirement presently exists in Article 480.

First level subdivisions (C), (D), and (E) (now (B), (C), and (D)) are editorially revised.

The 100 volt threshold in (C) (now (D)) is modified to address current practice.
Statement of Problem and Substantiation for Public Comment

A ground-fault detector is not required to disconnect the ungrounded conductors of a circuit. Disconnection of the ungrounded conductors is necessary in the event of a ground fault to ensure safety of the ESS. The ground fault detector should be capable of disconnecting the ungrounded conductors in the event of a ground fault or the ground-fault detector should be capable of providing a signal to a separate device capable of disconnecting the ungrounded conductors in the event of a ground fault.

Statement of Problem and Substantiation for Public Comment

The revisions that were accepted in 708.10(C)(2) change time-proven methods of providing fire and mechanical protection to these conductors without any substantiation of a problem with the existing requirements.

- The addition of the words “protected from fire for 2 hours” in 708.10(C)(2) is ambiguous and unenforceable for the concrete encasement allowance in new (3) which states: “the cable or raceway is encased in concrete”. It could be interpreted that any amount of concrete is sufficient or it could be interpreted that the concrete assembly has to be tested to prove that it has a 2 hour fire rating. The allowance for 2” of concrete encasement has been in this section of the Code for years and has been recognized as providing both mechanical and fire protection sufficient for this application. During the 2014 code cycle, a similar change was proposed using an International Building Code table showing fire resistive ratings of various concrete thicknesses as substantiation. It was defeated during the NFPA Technical Meetings. One of the supporters of the motion to reject the change and to allow the continued use of 2” of concrete was the past chairman of the ASCE SFP Committee on Structural Fire Protection who stated that the use of that table was a “complete and total misapplication”. This time there was no substantiation at all to remove the 2” requirement.

- The additional changes made to this section do not add clarity. One removes the option for 2 hour fire-rated assemblies, which should be retained, and one adds “a listed fire resistive cable system” which is not necessary. According to the UL On-Line Certification Directory Guide Information for fire resistive cables listed to UL 2196 (Category FHJR), they must be used as part of a classified Electrical Circuit Protective System (Category FHIT) so they are already included in existing (1) “be a listed electrical circuit protective system with a minimum 2-hour fire rating”.

**Committee Statement**

**Committee Action:** Rejected but see related SR

**Resolution:** The permission to use 2-inches of concrete was deleted in the first revision stage and is added back in this revision. The absence of a dimension for the depth of concrete would cause serious confusion in practical application.

Listed fire-rated assemblies with a minimum fire rating of 2 hours was deleted in the first revision stage and is added in this second revision. This means to achieve a 2 hour fire rating for COPS systems is time tested and commonly used.

Editorial revisions were made to the parent text and the list items to clarify the 2-hour requirement.
Public Comment No. 752-NFPA 70-2015 [Section No. 708.24(E)]

(E) Documentation:
The short-circuit current rating of the transfer equipment, based on the specific overcurrent protective device type and settings protecting the transfer equipment, shall be field marked on the exterior of the transfer equipment.

Statement of Problem and Substantiation for Public Comment

IEC's position is to delete 708.24(E) - (FR 7521)

The code already requires that equipment be installed according to available fault current, so adding this requirement is redundant. The installer/supplier already has the responsibility/liability to install the proper equipment based on the characteristics of the system. This proposal puts too much liability on the contractor/supplier because after installation various factors can change which will affect the available fault current. Feeders can be reworked, transformers can be changed with different impedance values, motor loads can be added to the existing system and similar factors that can change the available fault current. In the case of a lawsuit, the installer will have the burden of proof that the installation was done according to code and would result in unnecessary costs for defending an installation that was installed correctly, but that had variables change that are out of their control. A better proposal would be to require the owner to relabel the equipment after any alteration to the system.

Committee Statement

Committee Action: Rejected
Resolution: Typically Automatic Transfer Switches have several overcurrent protection options each with different short-circuit current ratings (analogous to withstand close on ratings) which can cause confusion for AHJ during inspection or for service provider when replacing overcurrent protection after installation. This requirement requires the installer to mark the equipment exterior with the short-circuit current rating of the automatic transfer switch based upon the specific overcurrent protective device type/rating. This clarifies to the inspector and service provider the specifics of the protection scheme, which is vital for safety.
Article 712, Interconnected Direct Current Microgrids (DC) Distribution Systems

Part I. General

712.1 Scope. This article applies to direct current microgrids distribution systems with interconnected direct current sources.

712.2 Definitions.

Interconnected Direct Current Microgrid (DC Microgrid) Distribution System. A direct current microgrid is a power distribution system consisting of one or more interconnected direct current sources, dc-dc converters, dc loads, and ac loads powered by dc-ac inverters. A dc microgrid is typically not directly connected to an ac primary source of electricity, but some dc microgrids interconnected via one or more dc-ac bidirectional converters or dc–ac inverters.

Informational Note: Direct current power sources include ac-dc converters (rectifiers), bidirectional dc-ac inverters/converters, photovoltaic systems, wind generators, energy storage systems (including batteries), and fuel cells. Interconnected Direct Current Distribution Systems are commonly called DC microgrids.

Grounded Two-Wire DC System

A two-wire dc power system is a system that has a direct connection or reference-ground between one of the current carrying conductors and the equipment grounding system.

Grounded Three-Wire DC System.

An interconnected direct current (DC) distribution system is a power distribution system consisting of one or more parallel connected dc power sources, dc-dc converters, dc loads, and ac loads powered by dc-ac inverters. A dc microgrid is typically not directly connected to an ac primary source of electricity, but some dc microgrids interconnected via one or more dc-ac bidirectional converters or dc–ac inverters.

Informational Note: Direct current power sources include ac-dc converters (rectifiers), bidirectional dc-ac inverters/converters, photovoltaic systems, wind generators, energy storage systems (including batteries), and fuel cells. Interconnected Direct Current Distribution Systems are commonly called DC microgrids.

Nominal Voltage.

A nominal value assigned to a circuit or system for the purpose of conveniently designating its dc voltage class (e.g., 24 volts dc, 190/380 volts dc, 380 volts dc).

Informational Note: The actual voltage at which a circuit operates can vary from the nominal voltage within a range that permits satisfactory operation of equipment.

Reference-Grounded DC System.

A microgrid system that is not solidly grounded but has a low-impedance electrical reference that maintains voltage to ground in normal operation. In the faulted state, the system becomes ungrounded or high-impedance grounded in order to limit fault current.

Resistively Grounded.

A dc power system with a high-impedance connection between the current carrying conductors and the equipment grounding system.

Primary DC Source.

A dc power source that supplies the majority of the dc load in a dc microgrid an interconnected dc distribution system.

Ungrounded DC System.

A dc power system that has no direct or resistive connection between the current carrying conductors and the equipment grounding system.

712.3 Other Articles. Wherever the requirements of other articles of this Code and Article 712 differ, the requirements of Article 712 shall apply. DC microgrids interconnected dc distribution systems that are interconnected through an inverter or bi-directional converter with ac electric power production sources shall, the interconnected ac portion of the system shall comply with Article 705.

712.4 Labeling and Listing. Any direct-current equipment used in a direct-current microgrid distribution system shall be listed and labeled for dc use.

(1) Disconnecting means

(2) Overcurrent and Ground Fault Protective devices

(3) Inverters, Converters, Rectifiers and other Power Conversion Equipment

(4) Panelboards, Switchboards, Switchgear, and Motor Control Centers

(5) Utilization Equipment
712.10 Directory.

A permanent directory denoting all dc electric power sources operating to supply the interconnected dc microgrid distribution system shall be installed at each source location capable of acting as the primary dc source.

Part II. Circuit Requirements

712.25 Identification of Circuit Conductors

(A)

Ungrounded circuit conductors in dc microgrid distribution systems shall be identified at termination, connection and splice points, according to the requirements of 210.5(C)(2) for branch circuits and 215.12(C)(2) for feeders. Continuous marking of conductors other than at the termination, connection and splice points shall not be required.

(B)

Ungrounded conductors of 6 AWG or smaller shall be permitted to be identified by polarity at all termination, connection, and splice points by marking, taping, or other approved means.

Exception to (A) and (B): In existing installations, where previous conductor identification exists, it is permissible to mark only the new conductor identification at the termination, connection and splice points.

712.30 System Voltage.

The system voltage of a dc microgrid distribution system shall be defined as follows:

1. The nominal voltage to ground for solidly-grounded systems
2. The nominal voltage to ground for reference-grounded systems where all conductors are disconnected from power sources when the reference ground is in the high-impedance, faulted state
3. The highest nominal voltage between conductors for resistively grounded dc systems and ungrounded dc systems.

Informational Note: Examples of nominal system voltages are 24 volts dc, 190/380 volts dc, 380 volts dc, and etc.

Part III. Disconnecting Means

712.34 DC Source Disconnecting Means.

The output of each dc source shall have a readily accessible, lockable disconnecting means. Disconnecting means shall be located in accordance with 690.13(A) for photovoltaic systems and adjacent to the source for other systems.

712.35 Disconnection of Ungrounded Conductors.

In solidly grounded two- and three-wire DC distribution systems, the disconnecting means shall simultaneously open all ungrounded conductors. In ungrounded, resistively grounded and reference-grounded systems, such devices shall open all current-carrying conductors.

712.37 Directional Current Devices.

Disconnecting means and protective and overcurrent devices that are designed for use in a single current direction shall only be used in the designated current direction.

Informational Note: Examples of directional current devices are magnetically quenched contactors and semiconductor switches in overcurrent devices. Contribution of fault current from multiple sources and selective coordination should be considered in the design of overcurrent protective devices used on interconnected DC distribution systems.

712.38 Loss of Direct Current Source.

Upon loss of primary dc source capacity, all dc electric power sources shall be automatically disconnected or curtailed from all ungrounded conductors of the dc primary source(s) and shall not be reconnected until the primary dc source capacity of the dc source(s) is restored. Individual premises dc sources shall be permitted to reconfigure and operate as a separate DC system(s) to supply loads that have been disconnected.

712.39 Response to Fire. In the event of a fire, the interconnected DC distribution system shall automatically shut down and de-energize the system.

Part IV. Wiring Methods

712.40 Identification for Branch Circuits and Feeder Circuits.

(A)

Wiring methods for dc microgrid distribution systems shall comply with the requirements of 210.5 for branch circuits and 215.12 for feeders.

(B)

DC microgrids operating at voltages greater than 300 volts dc shall be reference-grounded dc systems or resistively grounded dc systems.

Chapter 3.
712.52 System Grounding.
   (A) Direct-current microgrid distribution systems shall be grounded in accordance with 250.162.
   (B) DC microgrid distribution systems operating at voltages greater than 300 volts dc shall be reference-grounded dc systems or resistively grounded dc systems.

712.55 Ground Fault Protection of Equipment.
   (A) DC microgrid distribution systems operating at greater than 60 volts dc shall have ground fault protection that does all of the following:
      (1) Detects the fault
      (2) Indicates that a fault has occurred
      (3) For solidly grounded and reference-grounded systems, disconnects power from the faulted equipment
   (B) Ground fault equipment shall comply with 250.167.

712.57 Arc Fault Protection.
   DC microgrid distribution systems with a system voltage of greater than 60 volts shall be required to have arc fault protection for utilization circuits. Arc fault protection equipment shall be identified and listed for the purpose.
   Informational Note: 90.4 applies when suitable equipment for arc fault protection is not available.

Part VI. Marking

712.62 Panelboards.
Panelboards in dc microgrid systems shall be marked in accordance with 408.3.

712.65 Panelboards.
Panelboards in dc microgrid systems shall be marked in accordance with 408.3.

Available DC Fault Current.
   (A) Field Marking.
   Maximum available dc short-circuit current on the dc microgrid distribution system shall be field marked at the dc source(s). The field marking(s) shall include the date the fault-current calculation was performed and be of sufficient durability to withstand the environment involved.
   (B) Modifications.
   When modifications to the electrical installation occur that affect the maximum available fault current at the dc source(s), the maximum available fault current shall be verified or recalculated as necessary to ensure the equipment ratings are sufficient for the maximum available fault current at the line terminals of the equipment. The required field marking(s) in 712.65(A) shall be adjusted to reflect the new level of maximum available fault current.

Part VII. Systems with Multiple Sources

712.70 Overcurrent Protection.
Equipment and conductors connected to more than one electrical source shall have overcurrent devices located so as to provide protection from all sources.

712.72 Interrupting and Short-Circuit Current Rating.
Consideration shall be given to the contribution of fault currents from all interconnected power sources for the interrupting ratings and short-circuit current ratings of equipment in dc microgrid distribution systems. Overcurrent protective devices and equipment used within a dc microgrid distribution system shall have an interrupting rating at nominal circuit voltage or a short-circuit current rating sufficient for the available fault current at the line terminals of the equipment.

Part VIII. Systems over 1000 Volts

712.80 General.
Systems with a maximum voltage between conductors of over 1000 volts dc shall comply with Article 490 and other requirements applicable. Article 250 applicable to installations rated over 1000 volts.

Statement of Problem and Substantiation for Public Comment

The purpose of this comment is to offer a suggested resolution to the issues brought up in the committee statement and the concerns identified in the affirmative comments during the first revision. New Section 712.39 was added to address the shutdown of sources during fire conditions for first responders. 712.40 was re-written to address two issues with wiring methods. 712.25 was revised to address the identification and marking of DC conductors at accessible points and to address the existing identification of conductors and...
installation of new DC conductors. This identification also considered the color coding and it remains as the same in 210 branch circuits and 215 for feeders. 712.35 was considered, but it remains in 712 as original. The title of the Article was changed to Interconnected Direct Current (DC) Distribution Systems and the term microgrid as removed from the article except for a new information note on the definition of a Direct Current (DC) Distribution System. Use of the terms grounding and bonding were reviewed and corrected as necessary. In addition, the following topics of nominal voltage, disconnecting means and arc fault detection were reviewed and corrected as necessary.

Committee Statement
Committee Action: Rejected but see related SR
Resolution:
SR-3627-NFPA 70-2015; Public Comment 1174: CMP-13 retained the title “Direct Current Microgrids” in lieu of another title because this term is widely used and understood within the electrical industry. This term is used by IEEE, NEMA and the US Department of Energy. CMP-13 considered the proposed requirement to address response to a fire situation and identified that more information is needed. Public Comment 1016: Action on the SR for Article 712 satisfies the intent of the submitter. “Listed or labeled” was changed to “listed and labeled” and the title of 712.4 was changed for proper use of terminology. Public Comment 1017: Action on the SR for Article 712 satisfies the intent of the submitter. The panel did not remove “lockable” because this is a Chapter 7 article which supplements or modifies Chapters 1-4. Public Comment 1019: Action on the SR for Article 712 satisfies the intent of the submitter. Public Comment 1021: Action on the SR for Article 712 satisfies the intent of the submitter.

Statement:
The defined terms “Grounded Two-Wire DC System”, “Grounded Three-Wire DC System,” “Nominal Voltage”, “Reference-Grounded DC System”, “Resistively Grounded”, “Primary DC Source”, “Ungrounded DC System” are editorially modified for clarity, usability and compliance with the NEC style manual.

The definition of “Direct Current Microgrid” is modified to clarify that more than one interconnected source is required.

The last sentence in the defined term, “Reference-Grounded DC System” is deleted because it is a requirement.

712.4 is modified for clarity.

Editorial corrections are made and an Informational Note is added to 712.30 for clarity and usability.

712.34 is modified for clarity. The reference to 690.13(A) is deleted as there are many potential sources.

712.37 is modified for clarity. The listing and marking requirement is added to ensure that directional current devices are approved for the intended use.

Section 712.38 was deleted. The requirements in this section were intended to mirror the anti-islanding requirements for interconnected ac systems, in that distributed sources should not back-feed a de-energized utility grid. As there are presently no dc utility services, 712.38 only adds confusion and is unlikely to be relevant for many years until dc utility distribution systems are again implemented.

712.40 is deleted. First level subdivision (A) was just a reference to identification of DC conductors and the requirements in 210 and 215 apply as per section 90.3. First level subdivision (B) is deleted because it is referenced in 712.52.

712.52 is editorially revised to add first level subdivision titles.

In section 712.55, the term “ground fault protection” was changed to “ground fault detection.” The remainder of the section was editorially revised.

712.57 for arc fault protection of systems was modified to reference other requirements for arc fault protection in the NEC.

Part numbers were editorially revised.
Section 712.62 was modified from panelboards to distribution equipment and conductors.

Section 712.65, Panelboards, is deleted because it was duplicated.

Section 712.65, Available DC Fault Current, is modified for clarity and to specifically address “short circuit current” and to include the date of the marking.

The title of Part VII (now Part VI) is revised to “Protection” for clarity.

Section 712.70 is revised for clarity and usability.

Section 712.72 is modified for clarity to specifically address “short circuit current”.

Section 712.80 is revised for clarity and usability.
Article 712 Direct Current Microgrids

Part I. General

**712.1 Scope.**
This article applies to direct current microgrids.

**712.2 Definitions.**

**Direct Current Microgrid (DC Microgrid).**
A direct current microgrid is a power distribution system consisting of one or more interconnected dc power sources, dc-dc converters, dc loads, and ac loads powered by dc-ac inverters. A dc microgrid is typically not directly connected to an ac primary source of electricity, but some dc microgrids interconnect via one or more dc-ac bidirectional converters or dc–ac inverters.

Informational Note: Direct current power sources include ac-dc converters (rectifiers), bidirectional dc-ac inverters/converters, photovoltaic systems, wind generators, energy storage systems (including batteries), and fuel cells.

**Grounded Two-Wire DC System**
A two-wire dc power system that has a direct connection or reference-ground between one of the current carrying conductors and the equipment grounding system.

**Grounded Three-Wire DC System.**
A dc power system with a solid connection or reference-ground between the center point of a bipolar dc power source and the equipment grounding system.

**Nominal Voltage.**
A nominal value assigned to a circuit or system for the purpose of conveniently designating its dc voltage class (e.g., 24 volts dc, 190/380 volts dc, 380 volts dc). The actual voltage at which a circuit operates can vary from the nominal voltage within a range that permits satisfactory operation of equipment.

**Reference-Grounded DC System.**
A microgrid system that is not solidly grounded but has a low-impedance electrical reference that maintains voltage to ground in normal operation. In the faulted-state, the system becomes ungrounded or high-impedance grounded in order to limit fault current.

**Resistively Grounded.**
A dc power system with a high-impedance connection between the current carrying conductors and the equipment grounding system.

**Primary DC Source.**
A dc power source that supplies the majority of the dc load in a dc microgrid.

**Ungrounded DC System.**
A dc power system that has no direct or resistive connection between the current carrying conductors and the equipment grounding system.

**712.3 Other Articles.**
Wherever the requirements of other articles of this Code and Article 712 differ, the requirements of Article 712 shall apply. DC microgrids interconnected through an inverter or bi-directional converter with ac electric power production sources shall comply with Article 705.

**712.4 Labeling and Listing.**
Any direct-current equipment used in a direct-current microgrid shall be listed or labeled for dc use.

**712.10 Directory.**
A permanent directory denoting all dc electric power sources operating to supply the dc microgrid shall be installed at each source location capable of acting as the primary dc source.

Part II. Circuit Requirements

**712.25 Identification of Circuit Conductors**

**(A)**
Ungrounded circuit conductors in dc microgrids shall be identified according to the requirements of 210.5(C)(2) for branch circuits and 215.12(C)(2) for feeders.
Ungrounded conductors of 6 AWG or smaller shall be permitted to be identified by polarity at all termination, connection, and splice points by marking tape, tagging, or other approved means.

**712.30 System Voltage.**
The system voltage of a dc microgrid shall be defined as follows:

1. The nominal voltage to ground for solidly-grounded systems
2. The nominal voltage to ground for reference-grounded systems where all conductors are disconnected from power sources when the reference ground is in the high-impedance, faulted state
3. The highest nominal voltage between conductors for resistively grounded dc systems and ungrounded dc systems.

**Part III. Disconnecting Means**

**712.34 DC Source Disconnecting Means.**
The output of each dc source shall have a readily accessible, lockable disconnecting means. Disconnecting means shall be located in accordance with 690.13(A) for photovoltaic systems and adjacent to the source for other systems.

**712.35 Disconnection of Ungrounded Conductors.**
In solidly grounded two- and three-wire systems, the disconnecting means shall simultaneously open all ungrounded conductors. In ungrounded, resistively grounded and reference-grounded systems, such devices shall open all current-carrying conductors.

**712.37 Directional Current Devices.**
Disconnecting means and protective and overcurrent devices that are designed for use in a single current direction shall only be used in the designated current direction.

Informational Note: Examples of directional current devices are magnetically quenched contactors and semiconductor switches in overcurrent devices.

**712.38 Loss of Direct Current Source.**
Upon loss of primary dc source, all dc electric power sources shall be automatically disconnected from all ungrounded conductors of the dc primary source and shall not be reconnected until the primary dc source is restored. Individual premises dc sources shall be permitted to reconfigure and operate as the primary dc source in a stand-alone system(s) to supply loads that have been disconnected.

**Part IV. Wiring Methods**

**712.40 Identification for Branch Circuits and Feeder Circuits.**

(A) Wiring methods for dc microgrids shall comply with the requirements of 210.5 for branch circuits and 215.12 for feeders.

(B) DC microgrids operating at voltages greater than 300 volts dc shall be reference-grounded dc systems or resistively grounded dc systems.

**712.52 System Grounding.**

(A) Direct-current microgrids shall be grounded in accordance with 250.162.

(B) DC microgrids operating at voltages greater than 300 volts dc shall be reference-grounded dc systems or resistively grounded dc systems.

**712.55 Ground Fault Protection of Equipment.**

(A) DC microgrids operating at greater than 60 volts dc shall have ground fault protection that does all of the following:

1. Detects the fault
2. Indicates that a fault has occurred
3. For solidly grounded and reference-grounded systems, disconnects power from the faulted equipment

(B) Ground fault equipment shall comply with 250.167.

**712.57 Arc Fault Protection.**
DC microgrids with a system voltage of greater than 60 volts shall be required to have arc fault protection for utilization circuits. Arc fault protection equipment shall be identified and listed for the purpose.

Informational Note: 90.4 applies when suitable equipment for arc fault protection is not available.
Part VI. Marking

712.62 Panelboards.
Panelboards in dc microgrid systems shall be marked in accordance with 408.3.

712.65 Panelboards.
Panelboards in dc microgrid systems shall be marked in accordance with 408.3.

712.65 Available DC Fault Current.

(A) Field Marking.
Maximum available dc short-circuit current on the dc microgrid shall be field marked at the dc source. The field marking(s) shall include the date the fault-current calculation was performed and be of sufficient durability to withstand the environment involved.

(B) Modifications.
When modifications to the electrical installation occur that affect the maximum available fault current at the dc source, the maximum available fault current shall be verified or recalculated as necessary to ensure the equipment ratings are sufficient for the maximum available fault current at the line terminals of the equipment. The required field marking(s) in 712.65(A) shall be adjusted to reflect the new level of maximum available fault current.

Part VII. Systems with Multiple Sources

712.70 Overcurrent Protection.
Equipment and conductors connected to more than one electrical source shall have overcurrent devices located so as to provide protection from all sources.

712.72 Interrupting and Short-Circuit Current Rating.
Consideration shall be given to the contribution of fault currents from all interconnected power sources for the interrupting ratings and short-circuit current ratings of equipment in dc microgrid systems. Overcurrent protective devices and equipment used within a dc microgrid shall have an interrupting rating at nominal circuit voltage or a short-circuit current rating sufficient for the available fault current at the line terminals of the equipment.

Part VIII. Systems over 1000 Volts

712.80 General.
Systems with a maximum voltage between conductors of over 1000 volts dc shall comply with Article 490 and other requirements applicable to installations rated over 1000 volts.

Statement of Problem and Substantiation for Public Comment

Article 712 DC Microgrids is a new article that received many comments at ballot time, and will no doubt receive more during this public comment period.
The DC Microgrid Task Group (a sub group of the NEC DC Work Force) will meet and discuss the FD and public comments. It will also work closely with a task group appointed by the CMP13 chair to resolve issues in this new article. Two members of the TG are also principal members of CMP13.

Committee Statement

Committee Action: Rejected
Resolution: The submitter provides no proposed revisions. The comment does not comply with Section 4.4.4.4 of the NFPA Regulations Governing The Development of NFPA Standards to include proposed text in the Public Comment including the wording to be added, revised, or deleted.
Public Comment No. 1374-NFPA 70-2015 [ Section No. 712.2 ]

712.2 Definitions.

**Branch Circuit**
In a building containing a Direct Current Microgrid, with a connection to the AC utility grid through AC to DC conversion equipment, the branch circuit shall be defined to be the final point of AC wiring prior to the AC to DC conversion equipment.

**Direct Current Microgrid (DC Microgrid).**
A direct current microgrid is a power distribution system consisting of one or more interconnected dc power sources, dc-dc converters, dc loads, and ac loads powered by dc-ac inverters. A dc microgrid is typically not directly connected to an ac primary source of electricity, but some dc microgrids interconnect via one or more dc-ac bidirectional converters or dc–ac inverters.

Informational Note: Direct current power sources include ac-dc converters (rectifiers), bidirectional dc-ac inverters/converters, photovoltaic systems, wind generators, energy storage systems (including batteries), and fuel cells.

**Grounded Two-Wire DC System**
A two-wire dc power system that has a direct connection or reference-ground between one of the current carrying conductors and the equipment grounding system.

**Grounded Three-Wire DC System.**
A dc power system with a solid connection or reference-ground between the center point of a bipolar dc power source and the equipment grounding system.

**Nominal Voltage.**
A nominal value assigned to a circuit or system for the purpose of conveniently designating its dc voltage class (e.g., 24 volts dc, 190/380 volts dc, 380 volts dc). The actual voltage at which a circuit operates can vary from the nominal voltage within a range that permits satisfactory operation of equipment.

**Reference-Grounded DC System.**
A microgrid system that is not solidly grounded but has a low-impedance electrical reference that maintains voltage to ground in normal operation. In the faulted-state, the system becomes ungrounded or high-impedance grounded in order to limit fault current.

**Resistively Grounded.**
A dc power system with a high-impedance connection between the current carrying conductors and the equipment grounding system.

**Primary DC Source.**
A dc power source that supplies the majority of the dc load in a dc microgrid.

**Ungrounded DC System.**
A dc power system that has no direct or resistive connection between the current carrying conductors and the equipment grounding system.

Statement of Problem and Substantiation for Public Comment

Robert Bosch LLC recommends adding this definition to support the recommended changes to Article 712.70, which has the following justification: The installation of new DC circuits in new construction or the retrofit of specific existing wiring circuits to operate on a dc system, such as lighting circuits in commercial buildings, represents a tremendous improvement in utilization of renewable energy, overall system reliability, and resiliency to power outages with long-term cost savings and no impact to safety and reliability. Conversion to DC circuits also offers the opportunity to utilize high-resistance midpoint grounding schemes, which substantially reduces the chances of electric shock, since both current-carrying conductors have a high-resistance path to ground in this configuration.

Branch circuit overcurrent protective devices are rated for at least 5000 amperes interrupting rating, with the intention that this high level of AC current could theoretically be available from the utility grid on an instantaneous basis, depending on factors such as how far downstream the AC branch circuit is from the building utility service feed, wire gauge of feeders leading up to the AC branch, etc. However, DC building circuits are inherently limited in the amount of instantaneous AC grid current that may be converted to DC by the AC/DC conversion devices themselves. Therefore, utilizing branch circuit overcurrent protection devices on the AC circuits feeding AC/DC conversion electronics and utilizing supplemental overcurrent protection devices on the DC circuits feeding the DC devices within buildings provides a safe environment for DC building systems, since protection from the theoretical 5000 ampere instantaneous current from the utility grid still exists on the AC side of the conversion device. This is similar to overcurrent protection requirements for utilizing DC within machines and equipment, which means appropriate size and cost-effective DC supplemental overcurrent protection devices are already available to enable the introduction of DC Microgrids on a commercially viable scale. “Supplemental overcurrent devices utilized to feed DC load circuits shall be readily accessible” was added as a recommended exception to Article 240.10.
Committee Statement

Committee Action: Rejected

Resolution: The proposed definition would conflict with the definition of "branch circuit" in Article 100. That definition infers a branch circuit ends at the point in the wiring system where power is taken to supply utilization equipment. This is beyond the point in the circuit where the ac to dc conversion occurs.
### Public Comment No. 1016-NFPA 70-2015 [ Section No. 712.4 ]

**712.4 Labeling and Listing.**

Any *direct-current* equipment used in the *dc circuits* of a direct-current micro grid shall be listed or labeled for dc use.

### Statement of Problem and Substantiation for Public Comment

DC Microgrids may include AC inverters and other equipment which are not operating as dc. The requirements for dc listing should be limited to dc circuits

### Committee Statement

Committee Action: Rejected but see related SR

Resolution: SR-3627-NFPA 70-2015: Public Comment 1174: CMP-13 retained the title "Direct Current Microgrids" in lieu of another title because this term is widely used and understood within the electrical industry. This term is used by IEEE, NEMA and the US Department of Energy. CMP-13 considered the proposed requirement to address response to a fire situation and identified that more information is needed. Public Comment 1016: Action on the SR for Article 712 satisfies the intent of the submitter. "Listed or labeled" was changed to "listed and labeled" and the title of 712.4 was changed for proper use of terminology. Public Comment 1017: Action on the SR for Article 712 satisfies the intent of the submitter. The panel did not remove "lockable" because this is a Chapter 7 article which supplements or modifies Chapters 1-4. Public Comment 1019: Action on the SR for Article 712 satisfies the intent of the submitter.

The definition of "Direct Current Microgrid" is modified to clarify that more than one interconnected source is required.

The last sentence in the defined term, "Reference-Grounded DC System" is deleted because it is a requirement.

712.4 is modified for clarity.

Editorial corrections are made and an Informational Note is added to 712.30 for clarity and usability.

712.34 is modified for clarity. The reference to 690.13(A) is deleted as there are many potential sources.

712.37 is modified for clarity. The listing and marking requirement is added to ensure that directional current devices are approved for the intended use.

Section 712.38 was deleted. The requirements in this section were intended to mirror the anti-islanding requirements for interconnected ac systems, in that distributed sources should not back-feed a de-energized utility grid. As there are presently no dc utility services, 712.38 only adds confusion and is unlikely to be relevant for many years until dc utility distribution systems are again implemented.

712.40 is deleted. First level subdivision (A) was just a reference to identification of DC conductors and the requirements in 210 and 215 apply as per section 90.3. First level subdivision (B) is deleted because it is referenced in 712.52.

712.52 is editorially revised to add first level subdivision titles.
In section 712.55, the term "ground fault protection" was changed to "ground fault detection." The remainder of the section was editorially revised.

Section 712.57 for arc fault protection of systems was modified to reference other requirements for arc fault protection in the NEC.

Part numbers were editorially revised.

Section 712.62 was modified from panelboards to distribution equipment and conductors.

Section 712.65, Panelboards, is deleted because it was duplicated.

Section 712.65, Available DC Fault Current, is modified for clarity and to specifically address "short circuit current" and to include the date of the marking.

The title of Part VII (now Part VI) is revised to "Protection" for clarity.

Section 712.70 is revised for clarity and usability.

Section 712.72 is modified for clarity to specifically address "short circuit current".

Section 712.80 is revised for clarity and usability.
Public Comment No. 1086-NFPA 70-2015 [Section No. 712.25(A)]

(A) Ungrounded circuit conductors in dc microgrids 4 AWG or larger shall be identified according to the requirements of 210.5(C)(2) for branch circuits and 215.12(C)(2) for feeders.

Statement of Problem and Substantiation for Public Comment

The wording of 712.25(A) needs to be made more clear that it only applies to 4 AWG or larger so it is clear that 712.25(B) applies to 6 AWG and smaller. Otherwise it could be misinterpreted.

Submitter Information Verification

Submitter Full Name: MARVIN HAMON
Organization: HAMON ENGINEERING INC
Street Address: 
City: 
State: 
Zip: 
Submittal Date: Wed Sep 23 16:17:19 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The intent of the proposed revision is already covered in 210.5(C)(2) and 215.12(C)(2) and considered unnecessary.
Ungrounded conductors of 6 AWG or smaller shall be permitted to be identified by polarity at all termination, connection, and splice points by marking tape, tagging, or other approved means. A permanent, listed marking means such as sleeving or shrink tubing that is suitable for the conductor size, at all termination, connection, and splice points, with durably imprinted plus signs (+) or the word POSITIVE or POS for positive polarity and minus signs (-) or the word NEGATIVE or NEG for negative polarity. Marking tape shall not be permitted.

Statement of Problem and Substantiation for Public Comment

The proposed text allowed marking tape for wires smaller than #6 AWG. This is not considered good practice as tape tends to fall off small wires. This language is similar to that proposed for Articles 210 and 215 for dc system wire marking.

Submittal Date: Fri Sep 25 15:34:21 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The submitter did not provide adequate substantiation.
Ungrounded conductors of 6 AWG or smaller shall be permitted to be identified by polarity at all termination, connection, and splice points by marking tape, tagging, or other approved means for existing wiring circuits in buildings which are being converted to a dc system.

Statement of Problem and Substantiation for Public Comment

Robert Bosch LLC (Bosch) proposes an amendment to Article 712.25(B). This amendment clarifies how existing wiring circuits in buildings being converted to a dc system will be identified.

The reason for this amendment is that existing ungrounded conductors of 6 AWG or smaller in buildings being converted to a dc system can also be safely reused and identified per the same requirements as ungrounded conductors of 4 AWG or larger without any safety or reliability concerns per Article 210.5(C)(2). It is reasonable for the present requirements for 6 AWG or smaller in Article 210.5(C)(2)(a) and (b) to apply to new building construction, however for existing buildings it would in essence require perfectly usable existing wiring to be removed/disposed of and new wiring to be installed. This adds extra unnecessary waste/cost with the potential to create a less reliable and safe wiring environment through the extensive rework necessary, for zero benefit as the existing wiring does not need replacement and can be properly identified. The retrofit of specific existing wiring circuits to operate on a dc system, such as lighting circuits in commercial buildings, rather than having to install new wiring represents a tremendous improvement in utilization of renewable energy, overall system reliability, and resiliency to power outages with long-term cost effective savings and no impact to safety and reliability. Conversion to DC circuits also offers the opportunity to utilize high-resistance midpoint grounding schemes, which substantially reduces the chances of electric shock, since both current-carrying conductors have a high-resistance path to ground in this configuration.

Bosch has also proposed this same clarification to Articles 210.5(C)(2), 215.12(C)(2) and 712.40(B) that have the same requirements.

Submittal Date: Mon Sep 21 11:58:31 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The panel does not agree that the requirement applies only to existing buildings.
712.34  DC Source Disconnecting Means.

The output of each dc source shall have a readily accessible, lockable disconnecting means. Disconnecting means shall be located in accordance with 690.13(A) for photovoltaic systems and adjacent to the source for other systems.

Statement of Problem and Substantiation for Public Comment

The first sentence addresses the key requirement that all sources must have disconnects at their source. The special requirements for PV system disconnecting means is best addressed in 690, and adding additional, parallel requirements here does not add value but may cause confusion. Disconnecting means for other sources, where they may differ, is similarly best handled in articles specific to those sources. There is no benefit to adding a lockable requirement to all dc sources in this application, that is better and already addressed in the articles pertaining to the specific conditions presented by each dc source.

Section 712.72 is modified for clarity to specifically address “short circuit current”.

Section 712.80 is revised for clarity and usability.
Public Comment No. 1019-NFPA 70-2015 [Section No. 712.37]

712.37 Directional Current Devices.

Disconnecting means and protective and overcurrent devices that are designed listed or marked for use in a single current direction shall only be used in the designated current direction.

Informational Note: Examples of directional current devices are magnetically quenched contactors and semiconductor switches in overcurrent devices.

Statement of Problem and Substantiation for Public Comment

Some DC devices are designed and evaluated to break current only in one direction, and are evaluated or marked as such. The installer and AHJ cannot determine what a specific device may be designed to accommodate, only whether the device is listed and installed according to the manufacturer's instructions and markings.

712.52 is editorially revised to add first level subdivision titles.

In section 712.55, the term “ground fault protection” was changed to “ground fault detection.” The remainder of the section was editorially revised.

712.57 for arc fault protection of systems was modified to reference other requirements for arc fault protection in the NEC.

Part numbers were editorially revised.

Section 712.62 was modified from panelboards to distribution equipment and conductors.

Section 712.65, Panelboards, is deleted because it was duplicated.

Section 712.65, Available DC Fault Current, is modified for clarity and to specifically address “short circuit current” and to include the date of the marking.

The title of Part VII (now Part VI) is revised to “Protection” for clarity.

Section 712.70 is revised for clarity and usability.

Section 712.72 is modified for clarity to specifically address “short circuit current”.

Section 712.80 is revised for clarity and usability.
Loss of External Direct Current Source.

Upon loss of an external primary dc source, all dc microgrid electric power sources shall be automatically disconnected from all ungrounded conductors of the external dc primary source and shall not be reconnected until the external primary dc source is restored. Individual premises dc sources shall be permitted to reconfigure and operate as the primary dc source(s) in a stand-alone system(s) to supply loads that have been disconnected.

Statement of Problem and Substantiation for Public Comment

This section is supposed to be an "anti-islanding" clause for dc microgrids. Without the word "external", it had little meaning. The word microgrid was added to indicate internal sources. The phrase on loads was removed as there is no requirement to disconnect loads.

(B)

DC microgrids operating at voltages greater than 300 volts dc shall be reference grounded dc systems or resistively grounded dc systems.

Ungrounded conductors of 6 AWG or smaller shall be permitted to be identified by polarity at all termination, connection, and splice points by marking tape, tagging, or other approved means for existing wiring circuits in buildings which are being converted to a dc system.

Statement of Problem and Substantiation for Public Comment

Robert Bosch LLC (Bosch) proposes an amendment to Article 712.40(B). This amendment first corrects the requirements in Article 712.40(B) to reflect the language in the first draft meeting minutes of the NEC Code-Making Panel 13 that took place on January 12-17, 2015 (http://www.nfpa.org/Assets/files/AboutTheCodes/70/70_A2016_NEC-P13_FDagenda_1-15.pdf - Page 311) and also further clarifies how existing wiring circuits in buildings being converted to a dc system will be identified.

It seems as if the first draft of Article 712.40(B) accidentally replicated Article 712.52(B) instead of the language agreed upon in the meeting minutes. This should be corrected to reflect the meeting minutes.

The reason for the additional amendment is that existing ungrounded conductors of 6 AWG or smaller in buildings being converted to a dc system can also be safely reused and identified per the same requirements as ungrounded conductors of 4 AWG or larger without any safety or reliability concerns per Article 210.5(C)(2). It is reasonable for the present requirements for 6 AWG or smaller in Article 210.5(C)(2)(a) and (b) to apply to new building construction, however for existing buildings it would in essence require perfectly usable existing wiring to be removed/disposed of and new wiring to be installed. This adds extra unnecessary waste/cost with the potential to create a less reliable and safe wiring environment through the extensive rework necessary, for zero benefit as the existing wiring does not need replacement and can be properly identified. The retrofit of specific existing wiring circuits to operate on a dc system, such as lighting circuits in commercial buildings, rather than having to install new wiring represents a tremendous improvement in utilization of renewable energy, overall system reliability, and resiliency to power outages with long-term cost effective savings and no impact to safety and reliability. Conversion to DC circuits also offers the opportunity to utilize high-resistance midpoint grounding schemes, which substantially reduces the chances of electric shock, since both current-carrying conductors have a high-resistance path to ground in this configuration.

Bosch has also proposed this clarification to Articles 210.5(C)(2), 215.12(C)(2), and 712.25(B) that have the same requirements.

Committee Statement

Committee Action: Rejected
Resolution: The requirement in 712.40(B) is not related to the heading, "identification of circuits", and appears to be an accidental duplication of 712.52. Therefore, the proposed text replacing this section is unnecessary.
Public Comment No. 1022-NFPA 70-2015 [Section No. 712.55(A)]

(A) DC microgrids operating at greater than 60 volts dc shall have ground fault protection that does all of the following:

1. Detects the fault
2. Indicates that a fault has occurred
3. For solidly grounded and reference-grounded systems, disconnects power from the faulted circuit or equipment

Statement of Problem and Substantiation for Public Comment

Faults can occur in circuits as well as equipment, and language is revised more in keeping with NEC style guide.

Resolution: The action on the SR for Article 712 deleted 712.55(A)(3) making these revisions unnecessary.
712.57 Arc Fault Protection.
DC microgrids with a system voltage of greater than 60 volts shall be required to have arc fault protection for utilization circuits. Arc fault protection equipment shall be identified and listed for the purpose.

Informational Note: 90.4 applies when suitable equipment for arc fault protection is not available.

Statement of Problem and Substantiation for Public Comment

Bosch supports utilizing reliable arc fault protection equipment as it becomes available, and recommends to keep the specific comment in this section “Informational Note: 90.4 applies when suitable equipment for arc fault protection is not available.” This comment would allow beneficial DC systems to still be constructed as appropriate arc fault technology progresses, even if suitable arc fault technology is not initially available for every circuit application related to the DC systems.

Committee Statement
Committee Action: Rejected
Resolution: The submitter provides no proposed revisions. The comment does not comply with Section 4.4.4.4 of the NFPA Regulations Governing The Development of NFPA Standards to include proposed text in the Public Comment including the wording to be added, revised, or deleted.
712.70 Overcurrent Protection.

Equipment and conductors connected to more than one electrical source shall have overcurrent devices located so as to provide protection from all sources.

In a building containing a Direct Current Microgrid with a connection to the AC utility grid through AC to DC conversion equipment, the branch circuit shall be defined to be the final point of AC wiring prior to the AC to DC conversion equipment. Branch circuit overcurrent protection shall apply to the AC side of the circuit. The DC wiring shall be protected by appropriate supplemental overcurrent protection. Supplemental overcurrent devices utilized to feed DC load circuits shall be readily accessible.

Statement of Problem and Substantiation for Public Comment

Robert Bosch LLC (Bosch) proposes an amendment to Article 712.70 clarifying the appropriate overcurrent protection for DC circuits within buildings. The installation of new DC circuits in new construction or the retrofit of specific existing wiring circuits to operate on a dc system, such as lighting circuits in commercial buildings, represents a tremendous improvement in utilization of renewable energy, overall system reliability, and resiliency to power outages with long-term cost savings and no impact to safety and reliability. Conversion to DC circuits also offers the opportunity to utilize high-resistance midpoint grounding schemes, which substantially reduces the chances of electric shock, since both current-carrying conductors have a high-resistance path to ground in this configuration.

Branch circuit overcurrent protective devices are rated for at least 5000 amperes interrupting rating, with the intention that this high level of AC current could theoretically be available from the utility grid on an instantaneous basis, depending on factors such as how far downstream the AC branch circuit is from the building utility service feed, wire gauge of feeders leading up to the AC branch, etc. However, DC building circuits are inherently limited in the amount of instantaneous AC grid current that may be converted to DC by the AC/DC conversion devices themselves. Therefore, utilizing branch circuit overcurrent protection devices on the AC circuits feeding AC/DC conversion electronics and utilizing supplemental overcurrent protection devices on the DC circuits feeding the DC devices within buildings provides a safe environment for DC building systems, since protection from the theoretical 5000 ampere instantaneous current from the utility grid still exists on the AC side of the conversion device. This is similar to overcurrent protection requirements for utilizing DC within machines and equipment, which means appropriate size and cost-effective DC supplemental overcurrent protection devices are already available to enable the introduction of DC Microgrids on a commercially viable scale. “Supplemental overcurrent devices utilized to feed DC load circuits shall be readily accessible” was added as a recommended exception to Article 240.10.

Submitter Information Verification

Submitter Full Name: Andrew Yip
Organization: Robert Bosch LLC
Street Address: City: State: Zip:
Submittal Date: Fri Sep 25 02:11:27 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: Companion PC 1374 to revise the definition of branch circuit was rejected, and therefore the proposed revisions relative to the reference to branch circuit overcurrent protection and the allowable use of supplemental overcurrent devices are not supported.
712.72 Intermuting and Short-Circuit Current Rating.

Consideration shall be given to the contribution of fault currents from all interconnected power sources for the interrupting ratings and short-circuit current ratings of equipment in dc microgrid systems. Overcurrent protective devices and equipment used within a dc microgrid shall have an interrupting rating at nominal circuit voltage or a short-circuit current rating sufficient for the available fault current at the line terminals of the equipment.

Supplemental-type overcurrent devices shall be permitted to be used for branch circuit protection if the available fault current is less than the supplemental overcurrent device rating.

Statement of Problem and Substantiation for Public Comment

Branch circuit breakers fed with ac power from the utility grid must be rated for the available fault current which is often greater than 5000A. On dc microgrids however, the source of dc power is often ac-dc rectifiers and PV arrays with very limited peak current ability. This change states the opposite of the first paragraph - that in limited fault current cases, supplemental breakers rather than branch-circuit rated breakers can be used. Supplemental dc breakers are significantly smaller and less expensive than dc branch-rated breakers. They are still NRTL certified for the application.

Submittal Date: Fri Sep 25 15:47:41 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The substantiation that in limited fault (short circuit) current cases, supplemental breakers rather than branch circuit rated breakers can be used is not supported. The requirement for branch circuit protective devices is not based solely on the available short circuit current.
Scope.

This article covers remote-control, signaling, and power-limited circuits that are not an integral part of a device- or electric sign or of utilization equipment.

Informational Note: The circuits described herein are characterized by usage and electrical power limitations that differentiate them from electric light and power circuits; therefore, alternative requirements to those of Chapters 1 through 4, and Chapter 6 Article 600, are given with regard to minimum wire sizes, ampacity adjustment and correction factors, overcurrent protection, insulation requirements, and wiring methods and materials.

Statement of Problem and Substantiation for Public Comment

The sign industry has gone to great lengths to formalize their wiring methods for Class 2 wiring and power sources in Article 600 to be specific to signs and outline lighting and not to further confuse sign requirements from other wiring systems.

Submittal Date: Tue Sep 22 16:33:08 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The definition of “utilization equipment” is “equipment that utilizes electric energy for electronic, electromechanical, chemical, heating, lighting, or similar purposes.” Signs are utilization equipment, based on the definition in Article 100, so Class 2 and Class 3 power sources for signs already are covered in the scope of Article 725. Scope statements are under the authority of the NEC Correlating Committee and Panel 3 rejects this change.
Public Comment No. 460-NFPA 70-2015 [Section No. 725.3(C)]

(C) Ducts, Plenums, and Other Air-Handling Spaces.

Class 1, Class 2, and Class 3 circuits installed in ducts, plenums, or other space used for environmental air shall comply with 300.22.

Exception: As permitted in No. 1: Class 2 and Class 3 cables selected in accordance with Table 725.154 and installed in accordance with 725.135(B) shall be permitted to be installed in ducts specifically fabricated for environmental air.

Exception No. 2: Class 2 and Class 3 cables selected in accordance with Table 725.154 and installed in accordance with 725.135(C) shall be permitted to be installed in other spaces used for environmental air (plenums).

Statement of Problem and Substantiation for Public Comment

The recommended text clarifies that 725.135 has explicit rules for ducts [725.135(B)] and other spaces used for environmental air (plenums) [725.135(C)].

The current text does not comply with section 3.1.4.1 of the NEC Style Manual which requires that exceptions shall be written in complete sentences. Acceptance of the recommended text will result in compliance with the NEC Style manual.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-609-NFPA 70-2015
Statement: The First Revision FR 614 modified 300.22(B) by adding a new Exception indicating Class 2 and Class 3 cables are permitted in ducts specifically fabricated for environmental air with two conditions (a) The wiring methods or cabling systems shall be permitted only if necessary to connect to equipment or devices associated with the direct action upon, or sensing of the contained air and (b) The total length of such wiring methods or cabling systems shall not exceed 1.2 m (4 ft). These two conditions correspond to Section 4.3.4.2 in NFPA 90A—2015. The 2017 First Revision FR 614 in 300.22(B) reads as follows:

Exception: Wiring methods and cabling systems, listed for use in other spaces used for environmental air (plenums), shall be permitted to be installed in ducts specifically fabricated for environmental air-handling purposes under the following conditions:

(a) The wiring methods or cabling systems shall be permitted only if necessary to connect to equipment or devices associated with the direct action upon, or sensing of the contained air and

(b) The total length of such wiring methods or cabling systems shall not exceed 1.2 m (4 ft).

Class 2 or Class 3 plenum rated cable is acceptable in ducts specifically fabricated for environmental air but only where connecting to equipment used to sense or has direction action on the contained air and limited to a maximum of 4foot length based on NFPA 90A.
Public Comment No. 1397-NFPA 70-2015 [Section No. 725.3(K)]

(K) Installation of Conductors with Other Systems.
Installations shall comply with 300.8.
Installations for electric signs shall comply with 600.33

Statement of Problem and Substantiation for Public Comment

The clarify that Class 2 wiring for electric signs are controlled in Article 600 section 600.33 for their specific use. To again end the confusion with wiring between these articles.

Committee Statement

Committee Action: Rejected
Resolution: The reference for installations for signs in 725.3(K) is new information that has not had public review and the information in 600.33 should be reviewed to determine if Part I and Part III of Article 725 should be covered instead of just Part III.
Statement of Problem and Substantiation for Public Comment

Emergency responders and building occupant safety is at risk during building fires because people can become entangled and trapped in cable which has fallen out of molten or failing plastic supports/raceway. Even if people can free themselves from fallen cabling, this takes time which is otherwise needed to exit the building or fulfill the objectives of emergency personnel. The frequency of emergency responders becoming trapped in fallen cabling has become so common that firefighters have created and publicly distributed training videos on how to escape in these situations (http://www.fireengineering.com/topics/m/video/36928837/the-quick-release-method.htm?q=cable+entanglement) [1].

There have been documented fatalities due to cable entrapment both in the U.S. and England. In Memphis, Tennessee, in 1994, a fireman was entangled in cables that had fallen after the nonmetallic raceway collapsed due to the heat (http://www.fireengineering.com/articles/print/volume-148/issue-3/features/tragedy-in-a-residential-high-rise-memphis-tennessee.html [2]). More recently in England two firemen died due in part to being tangled in cabling that had fallen from plastic raceway in the ceiling of a Southampton residential building (http://www.bbc.co.uk/news/uk-england-hampshire-22126431 [3]). An article [4] in Electrical Contracting News identifies another recent incident in which a fireman died in Stevenage, Hertfordshire, after he became entangled in electrical cables which "had fallen after plastic trunking, the only support for the cables, melted and failed." Article [4] goes on to report that changes are in process to Great Britain’s Wiring Regulations (BS 7671 [5]) to ensure that “wiring systems in any escape route should be supported so that they are not subject to premature failure in a fire.” Revisions have already been made in a standard for fire alarm system cabling, BS 5839-1 [6], to require cable supports/raceway which will not collapse in a fire.

While the documented incidents involve firefighters, it is not even known how many building occupants may have died in the past either becoming entangled in fallen cabling, overcome by smoke/heat trying to remove a cabling obstruction, or forced to seek an alternate exit due to a significant amount of cabling obstruction.

NFPA 101 (Life Safety Code, 2012) [7] already addresses the requirement to maintain egress free from obstruction. Sections 7.1.10 and 7.1.10.1 (Means of Egress Reliability) state,

7.1.10.1 General. Means of egress shall be continuously maintained free of all obstructions or impediments to full instant use in case of fire or other emergency.

Sections 12.2.5.4, 12.2.5.4.2, and 12.2.5.4.3 (New Assembly Occupancies) and 13.2.5.4, 13.2.5.4.2, and 13.2.5.4.3 (Existing Assembly Occupancies) also emphasize this requirement.

12.2.5.4 General Requirements for Access and Egress Routes Within Assembly Areas.

12.2.5.4.2 Access and egress routes shall be maintained so that any individual is able to move without undue hindrance, on personal initiative and at any time, from an occupied position to the exits.

12.2.5.4.3 Access and egress routes shall be maintained so that crowd management, security, and emergency medical personnel are able to reach any individual at any time, without undue hindrance.

The solution that is easy to understand and enforce is a straightforward requirement regarding the allowable materials of a cable
support used above egress.

Melting temperatures of metallic and non-metallic materials are significantly different – compare the low carbon steel melting temperature of approximately 1450 °C versus 200-400 °C for many typical thermoplastics used in cable supports. This difference translates to a greater resistance to heat for steel which enables a metallic support to survive and carry load significantly longer than nonmetallic supports. The intent is not to eliminate the use of non-metallic supports/raceway in all applications, as they provide an appropriate and cost-effective option in other locations. The objective is to focus on egress which causes the highest risk to life safety.

In conclusion, there have been verifiable incidents in which firefighters have died due to entanglement from cabling fallen from plastic raceway that was weakened due to fire. This is not just a theoretical discussion or anecdotal evidence. In addition, NFPA 101 already emphasizes the need to maintain egress free from obstruction at all times, including during a fire. There is a clear opportunity in the NEC to improve consistency within NFPA Codes and save further loss of life.

Committee Statement

Committee Action: Rejected but held
Resolution: This should be addressed as a global issue within the NEC since it will affect many different articles throughout the NEC, such as many of the raceway and cable requirements in Chapter 3, Chapter 7, and Chapter 8 so it can only be dealt with initially by the NEC Correlating Committee. Panel 3 requests that the NEC Correlating Committee appoint a task group to address this issue before the next NEC cycle and also refer this to the Fire Protection Research Foundation for further research.
725.24 Mechanical Execution of Work.

Class 1, Class 2, and Class 3 circuits shall be installed in a neat and workmanlike manner. Cables and conductors installed exposed on the surface of ceilings and sidewalls shall be supported by the building structure in such a manner that the cable will not be damaged by normal building use. Such cables shall be supported by straps, staples, hangers, cable ties, or similar fittings designed and installed so as not to damage the cable. The installation shall also comply with 300.4(D).

Informational Note: Paint, plaster, cleaners, abrasives, corrosive residues, or other contaminants may result in an undetermined alteration of Class 2, Class 3 and PLTC cable properties.

Statement of Problem and Substantiation for Public Comment

Mr. Tim West of Superior Cable submitted PIs dealing with painting or contaminating cables for the following mechanical execution of work sections, 725.24, 760.24, 770.24, 800.24, and 820.24. CMP 3 resolved PI 4717 with the statement that section 110.12(B) applies and an additional reference is not substantiated. Section 110.12 applies to equipment:

110.12 Mechanical Execution of Work. Electrical equipment shall be installed in a neat and workmanlike manner.

The definition of equipment does not include cable.

Equipment. A general term, including fittings, devices, appliances, luminaires, apparatus, machinery, and the like used as a part of, or in connection with, an electrical installation.

We agree that painting or otherwise contaminating cables can change their properties, especially the fire protection properties of plenum cables. We prefer an informational note rather than mandatory text because the mandatory text recommended in the PIs is vague and unenforceable.

The informational note recommended by this Public Comment is based on the informational notes that were adopted by FR-4552 for 820.24 and FR-4592 for 830.24.

State: 
Zip: 
Submittal Date: Thu Jun 25 22:59:16 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: Section 110.12(B) does apply to internal parts of equipment and directly refers to busbars which are conductors. In addition, 110.11 states no conductors or equipment shall be installed where exposed to deteriorating agents so inserting an informational note is unnecessary.
Public Comment No. 1351-NFPA 70-2015 [New Section after 725.121]

Revise 725.122 to support Public Comment on Public Input 1837

725.121(C) The power supplies indentified in 725.121(A)(1),(A)(2),(A)(3), and (A)(4) shall have a nameplate with the voltage and current for each output connection.

Statement of Problem and Substantiation for Public Comment

Substantiation
The lack of nameplates on equipment listed to UL 60950 makes is difficult for specifiers, designers, installers, and inspectors to determine if the connected cable is robust enough to handle the required current without overheating.
The original intent of PI 3066 was to insure that new technologies being driven by Information Technology (IT) and video equipment that is sometimes refreshed in 18 month intervals and delivers power up to 100 watts can be installed on an existing cable plant. No name plate information for this refreshed equipment will prevent timely field validation that the existing cable is suitable.
This Public Comment adds a new requirement to 725.121 and supports the Public Comment on Public Input 1837.
The Panel Statement is correct that Chapter 9, Tables 11(A) & (B) require nameplates. However, the power sources listed to UL 60950 do not have a requirement for nameplates: voltage, VA, & current.
Section 725.121 has a list of what sources of power are permitted to power a Class 2 or 3 circuit, and Class 2 & 3 power supplies are required to comply with Chapter 9, Tables 11(A) & (B).

Submittal Date: Thu Sep 24 21:56:36 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-610-NFPA 70-2015
Statement: This new section addresses labeling of limited power circuit output connection points on listed IT equipment and listed industrial control panels and equipment. Bundling of large numbers of Class 2 conductors from IT servers and other similar IT and industrial equipment can create safety issues with very small current levels so having the output ports identified with the current and voltage rating is critical so the installer can connect the proper cable types. Labeling the output connections will permit the installer to have ready access to the current and voltage levels at the point of connection at the equipment, rather than internally within the equipment. The effective date was inserted to allow the manufacturers to comply with this requirement.
Public Comment No. 602-NFPA 70-2015 [Section No. 725.121(A)]

(A) Power Source.

The power source for a Class 2 or a Class 3 circuit shall be as specified in 725.121(A)(1), (A)(2), (A)(3), (A)(4), or (A)(5):

Informational Note No. 1: Informational Note Figure 725.121, No. 1 illustrates the relationships between Class 2 or Class 3 power sources, their supply, and the Class 2 or Class 3 circuits.

Informational Note No. 2: Table 11(A) and Table 11(B) in Chapter 9 provide the requirements for listed Class 2 and Class 3 power sources.

(1) A listed Class 2 or Class 3 transformer
(2) A listed Class 2 or Class 3 power supply
(3) Other listed equipment marked to identify the Class 2 or Class 3 power source

Exception No. 1 to (3): Thermocouples shall not require listing as a Class 2 power source.

Exception No. 2 to (3): Limited power circuits of listed equipment where these circuits have energy levels rated at or below the limits established in Chapter 9, Table 11(A) and Table 11(B).

Informational Note: Examples of other listed equipment are as follows:

(4) A circuit card listed for use as a Class 2 or Class 3 power source where used as part of a listed assembly
(5) A current-limiting impedance, listed for the purpose, or part of a listed product, used in conjunction with a non-power-limited transformer or a stored energy source, for example, storage battery, to limit the output current
(6) A thermocouple
(7) Limited voltage/current or limited impedance secondary communications circuits of listed industrial control equipment
(8) Listed audio/video information technology (computer), communications, and industrial equipment limited-power circuits.

Informational Note: One way to determine applicable requirements for listing of information technology (computer) equipment is to refer to UL 60950-1-2011, Standard for Safety of Information Technology Equipment. Another way to determine applicable requirements for listing of audio/video, information and communication technology equipment is to refer to UL 62368-1-2014, Safety of audio/video, information and communication technology equipment. Typically such circuits are used to interconnect data circuits for the purpose of exchanging information data. One way to determine applicable requirements for listing of industrial equipment is to refer to UL 61010-2-201, Safety requirements for electrical equipment for measurement, control, and laboratory use –Part 2-201: Particular requirements for control equipment, and/or UL 61800-5-1, Adjustable speed electrical power drive systems –Part 5-1: Safety requirements –Electrical, thermal and energy.

(9) A dry cell battery shall be considered an inherently limited Class 2 power source, provided the voltage is 30 volts or less and the capacity is equal to or less than that available from series connected No. 6 carbon zinc cells.

Statement of Problem and Substantiation for Public Comment

Including communications equipment as the source of a Class 2 circuit will cause confusion. The installation of communications equipment is covered in Chapter 8. Without a reference to this section from Chapter 8, the inclusion of communications equipment violates 90.3 which states:

"Chapter 8 covers communications systems and is not subject to the requirements of Chapters 1 through 7 except where the requirements are specifically referenced in Chapter 8."

The sole purpose of this Public Comment is to delete "communications". All the underlining was done by Terra View.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term “and labeled” was added after “listed” during the First Revision Stage, the words “and labeled” after “listed” be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms “listed” and “labeled,” most importantly, to clarify and establish a distinction between the terms “listed” and “labeled” which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of “listed and labeled.” As such, UL is submitting comments to request that the words “and labeled” be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer’s attestation that the product is in compliance with the appropriate standard. NRTL’s conduct factory surveillance of products, surveillance is one method to validate the manufacturer’s attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the “Listing” is not impacted, as the “listing” is created at the completion of the “original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards. The requirements for the UL Mark provide a requirement that the product is labeled, and the label contains the appropriate information. The NRTLs not meeting this requirement are not Safety Standard requirements, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

Public Comment No. 223-NFPA 70-2015 [Section No. 725.135(K)]

(K) Other Building Locations.

The following wires and cables shall be permitted to be installed in building locations other than the locations covered in 725.135(B) through (I):

2. A maximum of 3 m (10 ft) of exposed Type CL2X wires and cables in nonconcealed spaces
3. A maximum of 3 m (10 ft) of exposed Type CL3X wires and cables in nonconcealed spaces
4. Types CL2P, CL3P, CL2R, CL3R, CL2, CL3, and PLTC cables installed in the following:
   5. Plenum communications raceways
   6. Plenum cable routing assemblies
   7. Riser communications raceways
   8. Riser cable routing assemblies
   9. General-purpose communications raceways
  10. General-purpose cable routing assemblies

12. Type CMUC undercarpet communications wires and cables installed under carpet, floor covering, modular tiles, or planks. Carpet, floor covering, modular tiles, or planks shall be free-floating and shall use interlocking means to attach to each other or shall be adhered to the floor and shall be attached with release-type adhesives, but shall not be attached to the floor using grout, nails, or screws. modular flooring and planks.

Statement of Problem and Substantiation for Public Comment

This is a two-part Public Comment. The first part is an editorial clarification. The submitter of PI 621 also submitted PI 2623 to change the name of Type CMUC from “Undercarpet communications wire and cable” to “Under-floor Covering communications wire and cable”. CMP-16 resolved PI 2623 with the statement: “There is no need to change the section title and table and alter the listing requirements in order to accommodate the use of these cables under modular flooring and planks.” Accordingly, this Public Comment recommends text that permits the installation of Type CMUC “under carpet, modular flooring and planks”. Companion Public Comments have been submitted to make the same editorial change in 800.113.

The wording of the Resolution statement for PI 2623 is clear that the intent is to permit installation “under modular flooring and planks” in addition to installation under carpet. Therefore, it is hard to justify more stringent installation rules for communications under carpet wire and cable when used for Class 2 and Class 3 applications than when it is used for communications applications.

Note that this input has apparently been afflicted with the random underlining bug in the TerraWare software, and is not within the control of the submitter. This comment only deals with the installation of Type CMUC.

Public Comment No. 447-NFPA 70-2015 [Sections 725.135(K), 725.135(L), 725.135(M)]

Sections 725.135(K), 725.135(L), 725.135(M)

(K) Other Building Locations.

The following wires and cables shall be permitted to be installed in building locations other than the locations covered in 725.135(B) through (I):

2. A maximum of 3 m (10 ft) of exposed Type CL2X wires and cables in nonconcealed spaces
3. A maximum of 3 m (10 ft) of exposed Type CL3X wires and cables in nonconcealed spaces
4. Types CL2P, CL3P, CL2R, CL3R, CL2, CL3, and PLTC cables installed in the following:
   5. Plenum communications raceways
   6. Plenum cable routing assemblies
   7. Riser communications raceways
   8. Riser cable routing assemblies
   9. General-purpose communications raceways
   10. General-purpose cable routing assemblies

12. Type CMUC undercarpet communications wires and cables installed under carpet, floor covering, modular tiles, or planks. Carpet, floor covering, modular tiles, or planks shall be free-floating and shall use interlocking means to attach to each other or shall be adhered to the floor and shall be attached with release-type adhesives, but shall not be attached to the floor using grout, nails, or screws.

(L) Multifamily Dwellings.

The following wires and cables shall be permitted to be installed in multifamily dwellings in locations other than the locations covered in 725.135(B) through (I):

1. Types CL2P, CL3P, CL2R, CL3R, CL2, CL3, and PLTC wires and cables
2. Type CL2X wires and cables less than 6 mm (1/4 in.) in diameter in nonconcealed spaces
3. Type CL3X wires and cables less than 6 mm (1/4 in.) in diameter in nonconcealed spaces
4. Types CL2P, CL3P, CL2R, CL3R, CL2, CL3, and PLTC wires and cables installed in the following:
   5. Plenum communications raceways
   6. Plenum cable routing assemblies
   7. Riser communications raceways
   8. Riser cable routing assemblies
   9. General-purpose communications raceways
   10. General-purpose cable routing assemblies

12. Type CMUC undercarpet communications wires and cables installed under carpet, floor covering, modular tiles, or planks. Carpet, floor covering, modular tiles, or planks shall be free-floating and shall use interlocking means to attach to each other or shall be adhered to the floor and shall be attached with release-type adhesives, but shall not be attached to the floor using grout, nails, or screws.
One- and Two-Family Dwellings.

The following wires and cables shall be permitted to be installed in one- and two-family dwellings in locations other than the locations covered in 725.135(B) through (I):

1. Types CL2P, CL3P, CL2R, CL3R, CL2, CL3, and PLTC wires and cables
2. Type CL2X wires and cables less than 6 mm (1/4 in.) in diameter
3. Type CL3X wires and cables less than 6 mm (1/4 in.) in diameter

(4) Communications wires and Types CL2P, CL3P, CL2R, CL3R, CL2, CL3, and PLTC cables installed in the following:

5. Plenum communications raceways
6. Plenum cable routing assemblies
7. Riser communications raceways
8. Riser cable routing assemblies
9. General-purpose communications raceways
10. General-purpose cable routing assemblies

(12) Type CMUC undercarpet communications wires and cables installed under carpet, floor covering, modular tiles, or planks. Carpet, floor covering, modular tiles, or planks shall be free-floating and shall use interlocking means to attach to each other or shall be adhered to the floor and shall be attached with release-type adhesives, but shall not be attached to the floor using grout, nails, or screws.

Statement of Problem and Substantiation for Public Comment

The second sentence should be deleted because the National Electrical Code is not an installation code for flooring. It is outside the scope of the NEC to have mandatory installation requirements (shall, shall not) for flooring.

Submittal Date: Thu Aug 27 16:22:28 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: See SRs 620, 621, and 622 on these sections, which fulfill the intent of this comment. Type CMUC under carpet communication wire and cables are permitted to be installed under carpet with an installation expansion for modular flooring and planks. The installation instructions for free floating and interlocking does not necessarily apply to all kinds of modular flooring and planks and could be overly restrictive.
(L) Multifamily Dwellings.

The following wires and cables shall be permitted to be installed in multifamily dwellings in locations other than the locations covered in 725.135(B) through (I):

1. Types CL2P, CL3P, CL2R, CL3R, CL2, CL3, and PLTC wires and cables
2. Type CL2X wires and cables less than 6 mm (1/4 in.) in diameter in nonconcealed spaces
3. Type CL3X wires and cables less than 6 mm (1/4 in.) in diameter in nonconcealed spaces
4. Types CL2P, CL3P, CL2R, CL3R, CL2, CL3, and PLTC wires and cables installed in the following:
   5. Plenum communications raceways
   6. Plenum cable routing assemblies
   7. Riser communications raceways
   8. Riser cable routing assemblies
   9. General-purpose communications raceways
   10. General-purpose cable routing assemblies

6. Type CMUC undercarpet communications wires and cables installed under carpet, floor covering, modular tiles, or planks. Carpet, floor covering, modular tiles, or planks shall be free-floating and shall use interlocking means to attach to each other or shall be adhered to the floor and shall be attached with release-type adhesives, but shall not be attached to the floor using grout, nails, or screws. Modular flooring and planks.

Statement of Problem and Substantiation for Public Comment

This is a two-part Public Comment. The first part is an editorial clarification. The submitter of PI 621 also submitted PI 2623 to change the name of Type CMUC from “Undercarpet communications wire and cable” to “Under-floor Covering communications wire and cable”. CMP-16 resolved PI 2623 with the statement: “There is no need to change the section title and table and alter the listing requirements in order to accommodate the use of these cables under modular flooring and planks.”

The wording of the Resolution statement for PI 2623 is clear that the intent is to permit installation “under modular flooring and planks” in addition to installation under carpet. Accordingly, this Public Comment recommends text that permits the installation of Type CMUC “under carpet, modular flooring and planks”. Companion Public Comments have been submitted to make the same editorial change in 800.113.

The second part is the deletion of the installation requirements. Class 2 and Class 3 circuits do not have any greater safety risk than a communications circuit. Therefore, it is hard to justify more stringent installation rules for communications under carpet wire and cable when used for Class 2 and Class 3 applications than when it is used for communications applications.

Note that this input has apparently been afflicted with the random underlining bug in the TerraWare software, and is not within the control of the submitter. This comment only deals with the installation of Type CMUC.

Submitter Information Verification
Committee Statement

Committee Action: Accepted
Resolution: SR-622-NFPA 70-2015
Statement: Type CMUC under carpet communication wire and cables are permitted to be installed under carpet with an installation expansion for modular flooring and planks. The installation instructions for free floating and interlocking does not necessarily apply to all kinds of modular flooring and planks and could be overly restrictive.
Section 725.143: Support of Conductors.

Class 2 or Class 3 circuit conductors shall not be strapped, taped, or attached by any means to the exterior of any conduit or other raceway as a means of support. These conductors shall be permitted to be installed as permitted by 300.11(B)(2).

Section 725.144: Transmission of Power and Data.

The requirements of (A) and (B) shall apply to circuits that transmit power and data. The requirements in other Sections of Parts I and III shall apply, and 300.11 shall apply. The conductors that carry power shall be copper. The current in the power circuit shall not be permitted to exceed the current limit of the connectors.

(1) The ampacity ratings in Table 725.144 shall apply at an ambient temperature of 30°C (86°F).

(2) For ambient temperatures above 30°C (86°F), the correction factors of 310.15(B)(2) shall apply.

Informational Note: One example of the use of Class 2 (Type CL2R) cables is a network of closed circuit TV cameras using 24 AWG, 60°C, Type CL2R, Category 5e LAN (local area network) cables.

(B) Types CL3P-LP(xxA), CL2P-LP(xxA), CL3R-LP(xxA), CL2R-LP(xxA), CL3-LP(xxA), or CL2-LP(xxA). Types CL3P-LP(xxA), CL2P-LP(xxA), CL3R-LP(xxA), CL2R-LP(xxA), CL3-LP(xxA), or CL2-LP(xxA) shall be permitted to supply power to equipment at a current level up to the marked ampere limit(xxA) and to transmit data to the equipment. The cables shall comply with (1) through (3), as applicable.

Informational Note No. 1: The "(xxA)" in the text is the ampacity of each conductor in a cable based on the listing requirements in 725.179.

Informational Note No. 2: One installation example of a limited power cable is a cable listed and marked Type CL2-LP(0.5A), 23 AWG. Type CL2-LP(0.5), 23 AWG can be used in any location where a Type CL2 can be used and the cable would be suitable for carrying up to 0.5 A per conductor regardless of bundle size. If used in a 7 cable group, Table 725.144 indicates that the same cable could carry up to 1.2 amperes per conductor, because it is 23 AWG.

(1) Cables with the "-LP" suffix shall be permitted to installed in bundles, raceways, cable trays, communications raceways, or cable routing assemblies.

(2) Cables with the suffix "-LP(xxA)" shall follow the substitution hierarchy of Table 725.154(A) and Figure 725.154(A) for the type without the "-LP(xxA) suffix.

(3) System design shall be permitted by qualified persons under engineering supervision.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-611-NFPA 70-2015
Statement: The new section 725.144 and the accompanying table has been added based upon the Fact Finding Report on Power over Local Area Network type cables with additionally an introduction to new cable type LP that provides the current limitation due to cable bundling and some other installation considerations for power over Ethernet.
Public Comment No. 688-NFPA 70-2015 [Section No. 725.179]

725.179 Listing and Marking of Class 2, Class 3, and Type PLTC Cables.

Class 2, Class 3, and Type PLTC cables, installed as wiring methods within buildings, shall be listed as resistant to the spread of fire and other criteria in accordance with 725.179(A) through (J) and shall be marked in accordance with 725.179(A) through (J).

(A) Types CL2P and CL3P.

Types CL2P and CL3P plenum cable shall be listed as suitable for use in ducts, plenums, and other space for environmental air and shall be listed as having adequate fire-resistant and low-smoke-producing characteristics.

Informational Note: One method of defining a cable that is low-smoke producing and fire-resistant is that the cable exhibits a maximum peak optical density of 0.50 or less, an average optical density of 0.15 or less, and a maximum flame spread distance of 1.52 m (5 ft) or less when tested in accordance with NFPA 262-2015, Standard Method of Test for Flame Travel and Smoke of Wires and Cables for Use in Air-Handling Spaces.

(B) Types CL2R and CL3R.

Types CL2R and CL3R riser cables shall be marked as Type CL2R or CL3R, respectively, and be listed as suitable for use in a vertical run in a shaft or from floor to floor and shall be listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor.

Informational Note: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2012, Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts.

(C) Types CL2 and CL3.

Types CL2 and CL3 cables shall be marked as Type CL2 or CL3, respectively, and be listed as suitable for general-purpose use, with the exception of risers, ducts, plenums, and other space used for environmental air, and shall be listed as resistant to the spread of fire.

Informational Note: One method of defining resistant to the spread of fire is that the cables do not spread fire to the top of the tray in the UL flame exposure, vertical tray flame test in ANSI/UL 1685-2010, Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables. The smoke measurements in the test method are not applicable.

Another method of defining resistant to the spread of fire is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA vertical flame test for—cables in cable trays, as described in CSA C22.2 No. 0.3-M-2001, Test Methods for Electrical Wires and Cables.

(D) Types CL2X and CL3X.

Types CL2X and CL3X limited-use cables shall be marked as Type CL2X or CL3X, and be listed as suitable for use in dwellings and raceways and shall be listed as resistant to flame spread.

Informational Note: One method of determining that cable is resistant to flame spread is by testing the cable to the VW-1 (vertical wire) flame test in ANSI/UL 1581-2011, Reference Standard for Electrical Wires, Cables and Flexible Cords.

(E) Type PLTC.

Type PLTC nonmetallic-sheathed, power-limited tray cable shall be listed as being suitable for cable trays and shall consist of a factory assembly of two or more insulated conductors under a nonmetallic jacket. The insulated conductors shall be 22 AWG through 12 AWG. The conductor material shall be copper (solid or stranded). Insulation on conductors shall be rated for 300 volts. The cable core shall be two or more parallel conductors, one or more group assemblies of twisted or parallel conductors, or a combination thereof. A metallic shield or a metallized foil shield with drain wire(s) shall be permitted to be applied over the cable core, over groups of conductors, or both. The cable shall be listed as resistant to the spread of fire. The outer jacket shall be a sunlight- and moisture-resistant nonmetallic material. Type PLTC cable used in a wet location shall be listed for use in wet locations or have a moisture-impervious metal sheath.

Exception No. 1: Where a smooth metallic sheath, continuous corrugated metallic sheath, or interlocking tape armor is applied over the nonmetallic jacket, an overall nonmetallic jacket shall not be required. On metallic-sheathed cable without an overall metallic sheath, the information required in 310.120 shall be located on the nonmetallic jacket under the sheath.

Exception No. 2: Conductors in PLTC cables used for Class 2 thermocouple circuits shall be permitted to be any of the materials used for thermocouple extension wire.

Informational Note: One method of defining resistant to the spread of fire is that the cables do not spread fire to the top of the tray in the UL flame exposure, vertical tray flame test in ANSI/UL 1685-2010, Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables. The smoke measurements in the test method are not applicable.

Another method of defining resistant to the spread of fire is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA vertical flame test for—cables in cable trays, as described in CSA C22.2 No. 0.3-M-2001, Test Methods for Electrical Wires and Cables.

(F) Circuit Integrity (CI) Cable or Electrical Circuit Protective System.
Cables that are used for survivability of critical circuits under fire conditions shall meet either 725.179(F)(1) or (F)(2) as follows:

(1) Circuit Integrity (CI) Cables.

Circuit Integrity (CI) cables, specified in 725.179(A), (B), (C), and (E), and used for survivability of critical circuits, shall have the additional classification using the suffix “CI.” Circuit integrity (CI) cables shall only be permitted to be installed in a raceway where specifically listed and marked as part of an electrical circuit protective system as covered in 725.179(F)(2).

(2) Electrical Circuit Protective System.

Cables specified in 725.179(A), (B), (C), (E), and (F)(1) that are part of an electrical circuit protective system shall be identified with the protective system number and hourly rating printed on the outer jacket of the cable and installed in accordance with the listing of the protective system.

Informational Note No. 1: One method of defining circuit integrity (CI) cable or an electrical circuit protective system is by establishing a minimum 2-hour fire-resistive rating when tested in accordance with UL 2196-2012, Standard for Tests of Fire Resistive Cables.

Informational Note No. 2: UL guide information for electrical circuit protective systems (FHIT) contains information on proper installation requirements to maintain the fire rating.

(G) Class 2 and Class 3 Cable Voltage Ratings.

Class 2 cables shall have a voltage rating of not less than 150 volts. Class 3 cables shall have a voltage rating of not less than 300 volts. Class 2 and Class 3 cables shall have temperature rating of not less than 60°C (140°F).

(H) Class 3 Single Conductors.

Class 3 single conductors used as other wiring within buildings shall not be smaller than 18 AWG and shall be Type CL3. Conductor types described in 725.49(B) that are also listed as Type CL3 shall be permitted.

Informational Note: One method of defining resistant to the spread of fire is that the cables do not spread fire to the top of the tray in the UL flameexposure, verticaltray flame test in ANSI/UL 1685-2010, Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables. The smoke measurements in the test method are not applicable.

Another method of defining resistant to the spread of fire is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA verticalflame test for—cables in cable trays, as described in CSA C22.2 No. 0.3-M-2001, Test Methods for Electrical Wires and Cables.

(I) Limited Power Cables.

Limited power (LP) cables shall be listed as suitable for carrying power and data circuits up to a specified current limit for each conductor without exceeding the temperature rating of the cable where the cable is installed in cable bundles in free air or enclosed. The cables shall be marked with the suffix “-LP(xxA), where the xx is the current limit in amperes per conductor.

Informational Note: The “(xxA)” in the text is the ampacity (in Amperes) of each conductor in a cable. For example, 1 ampere Class 2 limited-power cables shall be marked CL2-LP (1.0), CL2R-LP (1.0A), or CL2-LP (1.0A), as applicable.

(J) Marking.

Cables shall be marked in accordance with 310.120(A)(2), (A)(3), (A)(4), (A)(5), and Table 725.179(K). Voltage ratings shall not be marked on the cables. Temperature rating shall be marked on the jacket of Class 2 and Class 3 cables that have a temperature rating exceeding 60°C (140°F).

Informational Note: Voltage markings on cables may be misinterpreted to suggest that the cables may be suitable for Class 1 electric light and power applications.

Exception: Voltage markings shall be permitted where the cable has multiple listings and a voltage marking is required for one or more of the listings.

Table 725.179(K) Cable Marking

Informational Note: Class 2 and Class 3 cable types are listed in descending order of fire resistance rating, and Class 3 cables are listed above Class 2 cables because Class 3 cables can substitute for Class 2 cables.

Additional Proposed Changes
Statement of Problem and Substantiation for Public Comment

This Public Comment is one of a series on cable heating due to the transmission of power and data using cables that are typically installed in bundles, raceways, cable trays, or cable routing assemblies.

To aid the panel in evaluation this Public Comment, the resolved Public Input 1838 is show at the end of the substantiation.  Note: References to other PI's are omitted.

Where there is an accumulation of cables are used for the transmission of power and data and are in open air or enclosed, the current in the conductors generate heat. The temperature may increase a sufficient amount to cause degradation of the cable insulation. The listing and marking is based on an extensive fact finding investigation by Underwriter’s Laboratories. The fact finding report is included for reference.

The UL fact finding investigation shows that the ampacities listed in Table 725.144 are accurate for 4-pair cables without the “-LP” suffix. However, in actual installations the quantity of cables routed together are often greater than 192 cables. The “LP” suffix provides a safety margin for installation in any quantity. In addition, it is important that the current rating of the cable is equal to or less than the nameplate rating of the power source.

Further, 20 AWG was not tested as, presently, 22 AWG is the largest conductor that will fit into a RJ 45 connector. Extensive testing at UL LLC has shown that large bundles of 4-pair cables with 22 AWG or smaller conductors may exceed their temperature rating with all conductors carrying 1 ampere, which is well below the 1.67 ampere maximum current permitted in a 60 volt, 100 VA circuit.

See the attached UL Fact Finding Report on Power over Local Area Network Type Cables (4-Pair Data / Communications Cables) for supporting data.

Submitter Information Verification

Submitter Full Name: Terry Peters
Organization: SPI
Affiliation: SPI
Street Address: 
City: 
State: 
Zip: 
Submittal Date: Thu Sep 17 11:09:26 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-615-NFPA 70-2015
Statement: Information on limited power cables is being added to the Code.
(B) Types CL2R and CL3R.

Types CL2R and CL3R riser cables shall be marked as Type CL2R or CL3R, respectively, and be listed as suitable for use in a vertical run in a shaft or from floor to floor and shall be listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor. Optionally, Types CL2R and CL3R riser cables shall be permitted to be marked as Type CL2R ST1 or CL3R ST1, respectively, if they are listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor and also listed as exhibiting limited smoke characteristics.

Informational Note 1: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2012, Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts.

Informational Note 2: One method of defining optional limited smoke characteristics for riser cables is that the cables exhibit a peak smoke release rate not exceeding 0.40 m²/s and a total smoke released not exceeding 150 m² when tested in accordance with the requirements of CSA "Vertical Flame Test - Cables in Cable Trays," as described in CSA C22.2 No. 0.3-M-2009, Test Methods for Wires and Cables.

Statement of Problem and Substantiation for Public Comment

Please reconsider the action on this public input and accept the public comment. Smoke obscuration is a key fire safety problem.

The reason that this additional optional listing and informational note are important is that there is no information in any of the test methods for fire propagation of cables how to test for smoke in riser cables. Such information is neither included in UL 1666 nor in CSA FT4 nor in UL 1685. Therefore there can be no standardized way for a manufacturer to demonstrate that a specific type of riser cables has lower smoke than typical riser cables. This is very different from the case of general purpose (or cable tray) cables. Both UL 1685 and CSA FT4 contain information on how to obtain "limited smoke" (meaning reduced smoke) cables that are general purpose cables. Therefore I understand the panel's objections to include optional markings for these cables. However, unless the code provides a systematic and standard way to determine what is a "limited smoke riser cable" the optional markings will not be able to be generated adequately.

A key aspect of wire and cable fire performance is smoke emission since it is well known that lack of visibility and smoke are serious problems in fire. In the NEC there is a designation for "low smoke cables", which are plenum-rated cables. There is also an optional designation of limited smoke cables, which is not required but applies to cable tray cables (tested to UL 1685 or CSA FT4). Riser cables are cables that are usually found in concealed spaces and it would be important to offer an optional marking for limited smoke riser cables, to distinguish them from standard riser cables. This is particularly useful for riser cables because, typically, riser cables are made with insulation and jacket materials that are very similar to CSA FT4 cables and also with materials that do not quite exhibit the flame and smoke characteristics of plenum cables. Therefore, manufacturers of materials who try to achieve a plenum cable rating, and can't quite make it, will often make their material slightly less safe from the point of view of smoke emission, in order to be able to save costs. This new optional marking would permit manufacturers to provide cables with both limited smoke and the flame spread characteristics of riser cable. The choice of criterion for the limited smoke riser cables (and the choice of designation) is based on the ST1 designation associated with the CSA FT4 test, when smoke emission is assessed.

This public comment is being proposed for all instances of riser cables and not public comment is proposed for optional markings of general purpose cables.

Submittal Date: Mon Sep 21 15:21:47 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: CL2R ST1 and CL3R ST1 are optional markings that are permitted to be used but are not required. CL2R or CL3R riser cables have not been required to have limited smoke characteristics in the NEC and there wasn’t any technical substantiation provided in either the Public Input or the Comment to require limited smoke characteristics. This is an option that is available but not covered by the mandatory text in 725.179 and could confuse the user into thinking it is mandatory.
Public Comment No. 454-NFPA 70-2015 [Section No. 760.3(B)]

(B) Ducts, Plenums, and Other Air-Handling Spaces.

Section 300.22. Where power-limited and non-power-limited fire alarm cables installed in ducts, or plenums or other spaces used for environmental air shall comply with 300.22.

Exception: As permitted in 760.53(B)(1) and (B)(2) and Table 760.154. No. 1: Power-limited fire alarm cables selected in accordance with Table 760.154 and installed in accordance with 760.135(B) shall be permitted to be installed in ducts specifically fabricated for environmental air.

Exception No. 2: Power-limited fire alarm cables selected in accordance with Table 760.154 and installed in accordance with 760.135(C) shall be permitted to be installed in other spaces used for environmental air (plenums).

Statement of Problem and Substantiation for Public Comment

The recommended text clarifies that 760.135 has explicit rules for power-limited fire alarm cables installed inducts (760.135(B)] and other spaces used for environmental air (plenums) [760.135(C)].

The current text does not comply with section 3.1.4.1 of the NEC Style Manual which requires that exceptions shall be written in complete sentences. Acceptance of the recommended text will result in compliance with the NEC Style manual.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-616-NFPA 70-2015
Statement: The existing exception was not in compliance with the NEC Style manual. The second exception was inserted to deal with power-limited fire alarm cables installed in other spaces used for environmental air (plenums). The reference to 300.22(B), Exception was inserted to ensure correlation with the requirements in NFPA 90A.
Public Comment No. 1685-NFPA 70-2015 [Section No. 760.24(A)]

(A) General.
Fire alarm circuits shall be installed in a neat workmanlike manner. Cables and conductors installed exposed on the surface of ceilings and sidewalls shall be supported by the building structure in such a manner that the cable will not be damaged by normal building use. Such cables shall be supported by straps, staples, cable ties, hangers, or similar fittings designed and installed so as not to damage the cable. The installation shall also comply with 300.4(D). Metallic means of support for flexible conduit and conductors shall be used in spaces above egress, which includes doorways, hallways, stairways, corridors, passageways, lobbies, landings, and equivalent spaces.

Informational note: Nonmetallic supports exhibit significant weakening and failure during fires which can affect the safety of occupants and emergency personnel entering and exiting buildings due to entanglement in fallen cable.

Statement of Problem and Substantiation for Public Comment

Emergency responders and building occupant safety is at risk during building fires because people can become entangled and trapped in cabling which has fallen out of molten or failing plastic supports/raceway. Even if people can free themselves from fallen cabling, this takes time which is otherwise needed to exit the building or fulfill the objectives of emergency personnel. The frequency of emergency responders becoming trapped in fallen cabling has become so common that firefighters have created and publicly distributed training videos on how to escape in these situations (http://www.fireengineering.com/topics/m/video/36928837/the-quick-release-method.htm?q=cable+entanglement) [1].

There have been documented fatalities due to cable entrapment both in the U.S. and England. In Memphis, Tennessee, in 1994, a fireman was entangled in cables that had fallen after the nonmetallic raceway collapsed due to the heat (http://www.fireengineering.com/articles/print/volume-148/issue-3/features/tragedy-in-a-residential-high-rise-memphis-tennessee.html [2]). More recently in England two firemen died due in part to being tangled in cabling that had fallen from plastic raceway in the ceiling of a Southampton residential building (http://www.bbc.co.uk/news/uk-england-hampshire-22126431 [3]). An article [4] in Electrical Contracting News identifies another recent incident in which a fireman died in Stevenage, Hertfordshire, after he became entangled in electrical cables which "had fallen after plastic trunking, the only support for the cables, melted and failed." Article [4] goes on to report that changes are in process to Great Britain's Wiring Regulations (BS 7671 [5]) to ensure that "wiring systems in any escape route should be supported so that they are not subject to premature failure in a fire." Revisions have already been made in a standard for fire alarm system cabling, BS 5839-1 [6], to require cable supports/raceway which will not collapse in a fire. While the documented incidents involve firefighters, it is not even known how many building occupants may have died in the past either becoming entangled in fallen cabling, overcome by smoke/heat trying to remove a cabling obstruction, or forced to seek an alternate exit due to a significant amount of cabling obstruction.

NFPA 101 (Life Safety Code, 2012) [7] already addresses the requirement to maintain egress free from obstruction. Sections 7.1.10 and 7.1.10.1 (Means of Egress Reliability) state,

7.1.10.1 General. Means of egress shall be continuously maintained free of all obstructions or impediments to full instant use in case of fire or other emergency.

Sections 12.2.5.4, 12.2.5.4.2, and 12.2.5.4.3 (New Assembly Occupancies) and 13.2.5.4, 13.2.5.4.2, and 13.2.5.4.3 (Existing Assembly Occupancies) also emphasize this requirement.

12.2.5.4 General Requirements for Access and Egress Routes Within Assembly Areas.
12.2.5.4.2 Access and egress routes shall be maintained so that any individual is able to move without undue hindrance, on personal initiative and at any time, from an occupied position to the exits.
12.2.5.4.3 Access and egress routes shall be maintained so that crowd management, security, and emergency medical personnel are able to reach any individual at any time, without undue hindrance.

13.2.5.4 General Requirements for Access and Egress Routes Within Assembly Areas.
13.2.5.4.2 Access and egress routes shall be maintained so that any individual is able to move without undue hindrance, on personal initiative and at any time, from an occupied position to the exits.
13.2.5.4.3 Access and egress routes shall be maintained so that crowd management, security, and emergency medical personnel are able to reach any individual at any time, without undue hindrance.

The solution that is easy to understand and enforce is a straightforward requirement regarding the allowable materials of a cable.
support used above egress.

Melting temperatures of metallic and non-metallic materials are significantly different – compare the low carbon steel melting temperature of approximately 1450 °C versus 200-400 °C for many typical thermoplastics used in cable supports. This difference translates to a greater resistance to heat for steel which enables a metallic support to survive and carry load significantly longer than nonmetallic supports. The intent is not to eliminate the use of non-metallic supports/raceway in all applications, as they provide an appropriate and cost-effective option in other locations. The objective is to focus on egress which causes the highest risk to life safety.

In conclusion, there have been verifiable incidents in which firefighters have died due to entanglement from cabling fallen from plastic raceway that was weakened due to fire. This is not just a theoretical discussion or anecdotal evidence. In addition, NFPA 101 already emphasizes the need to maintain egress free from obstruction at all times, including during a fire. There is a clear opportunity in the NEC to improve consistency within NFPA Codes and save further loss of life.

Bibliography:
Public Comment No. 75-NFPA 70-2015 [Section No. 760.24(A)]

(A) General.

Fire alarm circuits shall be installed in a neat workmanlike manner. Cables and conductors installed exposed on the surface of ceilings and sidewalls shall be supported by the building structure in such a manner that the cable will not be damaged by normal building use. Such cables shall be supported by straps, staples, cable ties, hangers, or similar fittings designed and installed so as not to damage the cable. The installation shall also comply with 300.4(D).

Informational Note: Paint, plaster, cleaners, abrasives, corrosive residues, or other contaminants may result in an undetermined alteration of NPLFA and PLFA cable properties.

Statement of Problem and Substantiation for Public Comment

Mr. Tim West of Superior Cable submitted PIs dealing with painting or contaminating cables for the following mechanical execution of work sections, 725.24, 760.24, 770.24, 800.24, and 820.24.

CMP 3 resolved PI 4721 with the statement that section 110.12(B) addresses the problem as stated in the substantiation for the PI. Section 110.12 applies to equipment:

110.12 Mechanical Execution of Work. Electrical equipment shall be installed in a neat and workmanlike manner.

The definition of equipment does not include cable.

Equipment. A general term, including fittings, devices, appliances, luminaires, apparatus, machinery, and the like used as a part of, or in connection with, an electrical installation.

We agree that painting or otherwise contaminating cables can change their properties, especially the fire protection properties of plenum cables. We prefer an informational note rather than mandatory text because the mandatory text recommended in the PIs is vague and unenforceable.

The informational note recommended by this Public Comment is based on the informational notes that were adopted by FR-4552 for 820.24 and FR-4592 for 830.24.

Statement of Problem and Substantiation for Public Comment

UL recognizes the Correlating Committee created a global First Correlating Revision (FCR) which directed that in all locations where the term "and labeled" was added after "listed" during the First Revision Stage, the words "and labeled" after "listed" be deleted, returning to previous text. UL understands that the Correlating Committee appointed a task group to address several issues involving the use of the terms "listed" and "labeled," most importantly, to clarify and establish a distinction between the terms "listed" and "labeled" which are often used interchangeably. UL supports the need for this task group. However, UL does not expect the work of this task group to affect the 2017 NEC regarding the issue of "listed and labeled." As such, UL is submitting comments to request that the words "and labeled" be added in various locations throughout the Code for the reasons expressed in the public inputs UL submitted on this issue. UL believes that these revisions will address an ongoing problem that should not wait until the 2020 NEC for resolution.

Subsequent to the Public Input Code Panel Meetings, UL has discussed this issue with its Electrical Council whose membership includes many AHJs. The proposed revisions to the NEC received general support from the membership. This issue was also discussed at a NEMA – NRTLs Forum held on August 14, 2015 at NEMA Headquarters. UL reiterated its support for the proposed revisions. The NRTLs represented at the meeting voiced no objection to the proposals.

The rationale for the revision was simple, to provide information to the AHJ regarding the suitability of equipment they encounter. The mark on the product is the manufacturer's attestation that the product is in compliance with the appropriate standard. NRTL's conduct factory surveillance of products, surveillance is one method to validate the manufacturer's attestation. Should a product be found not to be compliant the manufacturer has the option of removing the mark and shipping the product without the mark, or holding the shipment and bringing the product into compliance. In either case the "listing" is not impacted, as the "listing" is created at the completion of the "original" certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a "listing" has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL's do not consider a product as being listed unless it is also labeled. The UL White Book states that "Only those products bearing the appropriate UL Mark and the company's name, trade name, trademark or other authorized identification should be considered as being covered by UL's Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards." Again the requirements for the UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards. UL states that "Only those products bearing the appropriate UL Mark and the company's name, trade name, trademark or other authorized identification should be considered as being covered by UL's Certification, Listing, Classification and Follow-Up Service." The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards. The UL Mark requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL's have similar requirements.

Non–power-limited fire alarm cables installed as wiring within buildings shall be listed in accordance with 760.176(A) and (B) and as being resistant to the spread of fire in accordance with 760.176(C) through (F), and shall be marked in accordance with 760.176(G). Cable used in a wet location shall be listed for use in wet locations or have a moisture-impervious metal sheath. Non–power-limited fire alarm cables shall have a temperature rating of not less than 60°C (140°F).

Statement of Problem and Substantiation for Public Comment

The panel resolution statement “The Panel maintains that 60°C is established and is a listing requirement” is quite puzzling. We agree that it is the UL listing document since we stated in the PI “Requiring a temperature rating of 60°C (140°F) is consistent with the UL listing requirements for these cables.”

The temperature rating for these cables needs to be in the code. While we know it is in the UL listing, UL is not the only listing agency. Other listing agencies can choose a different temperature rating or not have one at all. The NEC is published in Spanish for use South and Central America. Can CMP 3 be sure that every country that uses the NEC has a 60°C rating?

Statement of Problem and Substantiation for Public Comment

Please reconsider the action on this public input and accept the public comment. Smoke obscuration is a key fire safety problem.

The reason that this additional optional listing and informational note are important is that there is no information in any of the test methods for fire propagation of cables how to test for smoke in riser cables. Such information is neither included in UL 1666 nor in CSA FT4 nor in UL 1685. Therefore there can be no standardized way for a manufacturer to demonstrate that a specific type of riser cables has lower smoke than typical riser cables. This is very different from the case of general purpose (or cable tray) cables. Both UL 1685 and CSA FT4 contain information on how to obtain “limited smoke” (meaning reduced smoke) cables that are general purpose cables. Therefore I understand the panel's objections to include optional markings for these cables. However, unless the code provides a systematic and standard way to determine what is a "limited smoke riser cable" the optional markings will not be able to be generated adequately.

A key aspect of wire and cable fire performance is smoke emission since it is well known that lack of visibility and smoke are serious problems in fire. In the NEC there is a designation for "low smoke cables", which are plenum-rated cables. There is also an optional designation of limited smoke cables, which is not required but applies to cable tray cables (tested to UL 1685 or CSA FT4). Riser cables are cables that usually are found in concealed spaces and it would be important to offer an optional marking for limited smoke riser cables, to distinguish them from standard riser cables. This is particularly useful for riser cables because, typically, riser cables are made with insulation and jacket materials that are very similar to CSA FT4 cables and also with materials that do not quite exhibit the flame and smoke characteristics of plenum cables. Therefore, manufacturers of materials who try to achieve a plenum cable rating, and can't quite make it, will often make their material slightly less safe from the point of view of smoke emission, in order to be able to save costs. This new optional marking would permit manufacturers to provide cables with both limited smoke and the flame spread characteristics of riser cable. The choice of criterion for the limited smoke riser cables (and the choice of designation) is based on the ST1 designation associated with the CSA FT4 test, when smoke emission is assessed.

This public comment is being proposed for all instances of riser cables and not public comment is proposed for optional markings of general purpose cables.

Committee Statement
Committee Action: Rejected
**Resolution:** NPLFR ST1 is an optional marking that is permitted to be used but are not required. NPLFR (riser) cables have not been required to have limited smoke characteristic in the NEC and there wasn't any technical substantiation provided in either the Public Input or the Comment to require limited smoke characteristics. This is an option that is available but not covered by the mandatory text in 760.176(D) and could confuse the user into thinking it is mandatory.
Public Comment No. 450-NFPA 70-2015 [Section No. 760.179(C)]

(C) Ratings.
The cable shall have a voltage rating of not less than 300 volts. The cable shall have a temperature rating of not less than 60°C (140°F).

Statement of Problem and Substantiation for Public Comment

PI 1609 was for 760.179(C). The title of 760.179 is Listing and Marking of PLFA Cables and Insulated Continuous Line-Type Fire Detectors. The panel resolution statement "The 60°C temperature rating is a listing requirement." is quite puzzling. It is a listing requirement; that's why it was proposed for the listing section, right next to the voltage rating. Cables have voltage ratings and temperature ratings; both of these listing requirements should be in the Code. Why include one, the voltage rating, and exclude the other, the temperature rating?
The temperature rating for these cables needs to be in the code. While we know it is in the UL listing, UL is not the only listing agency. Other listing agencies can choose a different temperature rating or not have one at all. The NEC is published in Spanish for use South and Central America. Can CMP 3 be sure that every country that uses the NEC has a 60°C rating?

Submittal Date: Thu Aug 27 16:36:15 EDT 2015

Committee Statement

Committee Action: Accepted
Resolution: SR-619-NFPA 70-2015
Statement: The temperature rating of these cables is required to provide pertinent information so the installer is aware of the temperature limitation of the conductors.
Type FPLR power-limited fire alarm riser cable shall be listed as being suitable for use in a vertical run in a shaft or from floor to floor and shall also be listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor. Optionally, Type FPLR riser cables shall be permitted to be marked as Type FPLR ST1 if they are listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor and also listed as exhibiting limited smoke characteristics.

Informational Note 1: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2012, Standard Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts.

Informational Note 2: One method of defining optional limited smoke characteristics for riser cables is that the cables exhibit a peak smoke release rate not exceeding 0.40 m$^2$/s and a total smoke released not exceeding 150 m$^2$ when tested in accordance with the requirements of CSA, “Vertical Flame Test - Cables in Cable Trays,” as described in CSA C22.2 No. 0.3-M-2009, Test Methods for Wires and Cables.

Statement of Problem and Substantiation for Public Comment

Please reconsider the action on this public input and accept the public comment. Smoke obscuration is a key fire safety problem.

The reason that this additional optional listing and informational note are important is that there is no information in any of the test methods for fire propagation of cables how to test for smoke in riser cables. Such information is neither included in UL 1666 nor in CSA FT4 nor in UL 1685. Therefore there can be no standardized way for a manufacturer to demonstrate that a specific type of riser cables has lower smoke than typical riser cables. This is very different from the case of general purpose (or cable tray) cables. Both UL 1685 and CSA FT4 contain information on how to obtain "limited smoke" (meaning reduced smoke) cables that are general purpose cables. Therefore I understand the panel's objections to include optional markings for these cables. However, unless the code provides a systematic and standard way to determine what is a "limited smoke riser cable" the optional markings will not be able to be generated adequately.

A key aspect of wire and cable fire performance is smoke emission since it is well known that lack of visibility and smoke are serious problems in fire. In the NEC there is a designation for "low smoke cables", which are plenum-rated cables. There is also an optional designation of limited smoke cables, which is not required but applies to cable tray cables (tested to UL 1685 or CSA FT4). Riser cables are cables that usually are found in concealed spaces and it would be important to offer an optional marking for limited smoke riser cables, to distinguish them from standard riser cables. This is particularly useful for riser cables because, typically, riser cables are made with insulation and jacket materials that are very similar to CSA FT4 cables and also with materials that do not quite exhibit the flame and smoke characteristics of plenum cables. Therefore, manufacturers of materials who try to achieve a plenum cable rating, and can't quite make it, will often make their material slightly less safe from the point of view of smoke emission, in order to be able to save costs. This new optional marking would permit manufacturers to provide cables with both limited smoke and the flame spread characteristics of riser cable. The choice of criterion for the limited smoke riser cables (and the choice of designation) is based on the ST1 designation associated with the CSA FT4 test, when smoke emission is assessed.

This public comment is being proposed for all instances of riser cables and not public comment is proposed for optional markings of general purpose cables.

Committee Statement

Committee Action: Rejected

Committee Report
Resolution:  FPLR ST1 is an optional marking that is permitted to be used but are not required. FPLR (riser) cables have not been required to have limited smoke characteristic in the NEC and there wasn’t any technical substantiation provided in either the Public Input or the Comment to require limited smoke characteristics. This is an option that is available but not covered by the mandatory text in 760.179(E) and could confuse the user into thinking it is mandatory.
Exposed (to Accidental Contact):
A conductive optical fiber cable in such a position that, in case of failure of supports or insulation, contact between the cable's non-current-carrying conductive members and an electrical circuit may result.

Informational Note: See Part I of Article 100 for two other definitions of Exposed.

Statement of Problem and Substantiation for Public Comment

The term “Exposed” has multiple meanings throughout the NEC: uncovered and capable of being touched by persons, susceptible to physical damage, e.g., wiring attached to a surface, susceptible to power influences such as contact or induction, and susceptible to lightning influences, either a direct ‘hit’, induction or ground potential rise. Hence, the Informational Note provides clarity and should be maintained.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4507-NFPA 70-2015
Statement: The term “exposed” has multiple meanings throughout the NEC: uncovered and capable of being touched by persons, susceptible to physical damage, e.g., wiring attached to a surface, susceptible to power influences such as contact or induction, and susceptible to lightning influences, either a direct ‘hit’, induction or ground potential rise. Hence, the informational note provides clarity and has been maintained.
**Public Comment No. 444-NFPA 70-2015 [ Definition: Point of Entrance. ]**

**Point of Entrance.**
The point within a building at which the optical fiber cable emerges from an external wall, or from a concrete floor slab, from rigid metal conduit (RMC), or from intermediate metal conduit (IMC).

**Statement of Problem and Substantiation for Public Comment**

Panel action on FR 4521 for 770.48 added “The point of entrance shall be permitted to be extended from the penetration of the external wall or floor slab to the point of emergence from the rigid metal conduit (RMC) or intermediate metal conduit (IMC) by continuously enclosing the entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC).”

This action is confusing unless the definition of point of entrance is modified to remove the text about the point of entrance being the point where the cable emerges from the RMC or the IMC.

This PC is offered as an alternative to PC 455. Similar PC are made for Article 800 sections and Article 820 sections.

**Committee Statement**

Committee Action: Accepted
Resolution: SR-4508-NFPA 70-2015
Statement: The definition of “point of entrance” is simplified and potential confusion is avoided by locating the information regarding the application of rigid metal conduit (RMC) and intermediate metal conduit (IMC) in 770.48(A), Conductive and Nonconductive Cable.
Public Comment No. 173-NFPA 70-2015 [Section No. 770.24]

770.24  Mechanical Execution of Work.
Optical fiber cables shall be installed in a neat and workmanlike manner. Cables installed exposed on the surface of ceilings and sidewalls shall be supported by the building structure in such a manner that the cable will not be damaged by normal building use. Such cables shall be secured by hardware, including straps, staples, cable ties, hangers, or similar fittings designed and installed so as not to damage the cable. The installation shall also conform to 300.4(D) and 300.11. Nonmetallic cable ties and other nonmetallic cable accessories used to secure and support cables in other spaces used for environmental air (plenums) shall be listed as having low smoke and heat release properties in accordance with 800.170(C).

Informational Note No. 1: Accepted industry practices are described in ANSI/NECA/BICSI 568-2006, Standard for Installing Commercial Building Telecommunications Cabling; ANSI/NECA/FOA 301-2015, Standard for Installing and Testing Fiber Optic Cables; and other ANSI-approved installation standards.

Informational Note No. 2: See 4.3.11.2.6.5 and 4.3.11.5.5.6 of NFPA 90A-2015, Standard for the Installation of Air-Conditioning and Ventilating Systems, for discrete combustible components installed in accordance with 300.22(C).

Informational Note No. 3: For additional information regarding overhead wires and cables, see ANSI C2-2012, National Electric Safety Code, Part 2, Safety Rules for Overhead Lines.

Statement of Problem and Substantiation for Public Comment

Make no changes to the text of 770.24 with respect to the reference to 300.4(D) as contained in the First Draft Report. We do not agree with the Committee Statement to revise the text “… to reference 300.4 in its entirety as optical fiber cables need to be protected from all sources of damage”. No technical substantiation has been presented to support the additional requirements. The Committee Statement “optical fiber cables need to be protected from all sources of damage” does not constitute adequate technical substantiation. The requirements of 300.4 are appropriate for power wiring, not optical fiber cables. Neither a fire nor electrical safety hazard has been identified to justify expanding the requirements of 770.24. Optical fiber cables carry no power and pose neither a fire nor electrical safety hazard.

Note that Sections 725.24 and 760.24 under the purview of Code-making Panel 3 and addressing low voltage signaling and fire alarm systems, respectively, do not contain the additional requirements and continue to reference only 300.4(D). These systems also utilize optical fiber cables. Applying the full requirements of 300.4 in 770.24 will create a correlation issue not only with 725.24 and 760.24, but also with 90.1 (Purpose) – “… safeguarding of persons and property from hazards arising from the use of electricity”. There is no electricity, hence no electrical hazard. Finally, we believe there is an error in the 2014 NEC with respect to 770.24. The Correlating Committee, in reviewing the formal Panel 16 ballot on Comments 16-16 and 16-18, directed that “… this Comment and Proposal 16-40 be reported as “Reject” because less than two-thirds of the members eligible to vote have voted in the affirmative”. This action by the Correlating Committee should have restored the NEC to the 2011 text that referenced only 300.4(D).

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4509-NFPA 70-2015
Statement: Article 770 deals with all types of optical fiber cable installations and not just installations dealing with communications systems, then the installation requirements for optical fiber cables should comply with all of Section 300.4. Optical fiber cables is used for life safety applications such as for fire alarm systems, some building system controls and industrial process controls.

Informational Note No. 1 was revised to eliminate the word “accepted” because it is generally thought of being associated with the authority having jurisdiction.
New Informational Note No. 3 identifies possible contamination of optical fiber cables during the construction process by paint or other foreign materials, potentially altering the fire resistance, smoke generating or other properties that are part of the cable listing requirements.
770.24  Mechanical Execution of Work.

Optical fiber cables shall be installed in a neat and workmanlike manner. Cables installed exposed on the surface of ceilings and sidewalls shall be supported by the building structure in such a manner that the cable will not be damaged by normal building use. Such cables shall be secured by hardware, including straps, staples, cable ties, hangers, or similar fittings designed and installed so as not to damage the cable. The installation shall also conform to 300.4(D) and 300.11. Nonmetallic cable ties and other nonmetallic cable accessories used to secure and support cables in other spaces used for environmental air (plenums) shall be listed as having low smoke and heat release properties in accordance with 800.170(C).

Informational Note No. 1: Accepted industry practices are described in ANSI/NECA/BICSI 568-2006, Standard for Installing Commercial Building Telecommunications Cabling; ANSI/NECA/FOA 301-2015, Standard for Installing and Testing Fiber Optic Cables; and other ANSI-approved installation standards.

Informational Note No. 2: See 4.3.11.2.6.5 and 4.3.11.5.5.6 of NFPA 90A-2015, Standard for the Installation of Air-Conditioning and Ventilating Systems, for discrete combustible components installed in accordance with 300.22(C).

Informational Note No. 3: For additional information regarding overhead wires and cables, see ANSI C2-2012, National Electric Safety Code, Part 2, Safety Rules for Overhead Lines.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs that further consideration be given to the comments expressed in voting on FR 4518.

Committee Statement

| Committee Action: | Rejected but see related SR |
| Resolution:       | SR-4509-NFPA 70-2015       |
| Statement:        | Article 770 deals with all types of optical fiber cable installations and not just installations dealing with communications systems, then the installation requirements for optical fiber cables should comply with all of Section 300.4. Optical fiber cables is used for life safety applications such as for fire alarm systems, some building system controls and industrial process controls. Informational Note No. 1 was revised to eliminate the word "accepted" because it is generally thought of being |

2033 of 2282 11/19/2015 12:04 PM
associated with the authority having jurisdiction.

New Informational Note No. 3 identifies possible contamination of optical fiber cables during the construction process by paint or other foreign materials, potentially altering the fire resistance, smoke generating or other properties that are part of the cable listing requirements.
Public Comment No. 47-NFPA 70-2015 [Section No. 770.44(B)]

(B) Above Roofs.

Outside plant optical fiber cables shall have a vertical clearance of not less than 2.5 m (8 ft) from all points of roofs above which they pass.

Exception No. 1: The requirement of 770.44(B) shall not apply to auxiliary buildings such as garages and the like.

Exception No. 2: A reduction in clearance above only the overhanging portion of the roof to not less than 450 mm (18 in.) shall be permitted if (a) not more than 1.2 m (4 ft) of optical fiber cable service drop cable passes above the roof overhang, and (b) the cable is terminated at a through- or above-the-roof raceway or approved support.

Exception No. 3: Where the roof has a slope of not less than 100 mm in 300 mm (4 in. in 12 in.), a reduction in clearance to not less than 900 mm (3 ft) shall be permitted.

Informational Note: For additional information regarding overhead wires and cables, see ANSI C2-2012, National Electric Safety Code, Part 2, Safety Rules for Overhead Lines.

Statement of Problem and Substantiation for Public Comment

Corrected SDO reference in the informational note for exception #3.

Public Comment No. 177-NFPA 70-2015 [Section No. 770.48(A)]

(A) Conductive and Nonconductive Cables.

Unlisted conductive and nonconductive outside plant optical fiber cables shall be permitted to be installed in building spaces, other than risers, ducts used for environmental air, plenums used for environmental air, and other spaces used for environmental air, where the length of the cable within the building, measured from its point of entrance, does not exceed 15 m (50 ft) and the cable enters the building from the outside and is terminated in an enclosure.

The point of entrance shall be permitted to be extended from the penetration of the external wall or floor slab to the point of emergence from the rigid metal conduit (RMC) or intermediate metal conduit (IMC) by continuously enclosing the entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC).

Informational Note No. 1: Splice cases or terminal boxes, both metallic and plastic types, typically are used as enclosures for splicing or terminating optical fiber cables.

Informational Note No. 2: The point of entrance may be extended further into the building by continuing to enclose the entrance cable in rigid metal conduit (RMC) or intermediate metal conduit (IMC).

Statement of Problem and Substantiation for Public Comment

The proposed added text “The point of entrance shall be permitted to be extended from the penetration of the external wall or floor slab to the point of emergence from the rigid metal conduit (RMC) or intermediate metal conduit (IMC) by continuously enclosing the entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC).” is a cumbersome and run-on sentence that is both confusing and redundant. The definition, “point of entrance”, currently and adequately defines RMC and IMC as acceptable vehicles establishing the point of entrance. If the Panel feels it is necessary to further clarify the use of RMC and IMC, greater clarity is provided by a simple Informational Note such as “The point of entrance may be extended further into the building by continuing to enclose the entrance cable in rigid metal conduit (RMC) or intermediate metal conduit (IMC).”

Resolution: SR-4511-NFPA 70-2015
Statement: The text is appropriate as a requirement. According to the NEC Style Manual Section 3.1.3, informational notes shall not be written in mandatory language and shall not contain requirements, make interpretations, or make recommendations.
Public Comment No. 455-NFPA 70-2015 [Section No. 770.48(A)]

(A) Conductive and Nonconductive Cables.

Unlisted conductive and nonconductive outside plant optical fiber cables shall be permitted to be installed in building spaces, other than risers, ducts used for environmental air, plenums used for environmental air, and other spaces used for environmental air, where the length of the cable within the building, measured from its point of entrance, does not exceed 15 m (50 ft) and the cable enters the building from the outside and is terminated in an enclosure. The point of entrance shall be permitted to be extended from the

Informational Note No. 1: Splice cases or terminal boxes, both metallic and plastic types, typically are used as enclosures for splicing or terminating optical fiber cables.

Informational Note No. 2: Continuously enclosing entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC) extends the point of entrance from penetration of the external wall or floor slab to the point of emergence from the rigid metal conduit (RMC) or intermediate metal conduit (IMC) by continuously enclosing the entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC).

Informational Note: Splice cases or terminal boxes, both metallic and plastic types, typically are used as enclosures for splicing or terminating optical fiber cables.

Statement of Problem and Substantiation for Public Comment

The added text about extending the point of entrance was recommended to be an informational note in PI 1561. If the panel had adopted that recommendation, it would have avoided the confusion of permitting the extension of the point of entrance by using RMC or IMC when the point of entrance is already defined as the point emergence from RMC or IMC.

This PC is offered as an alternative to PC 444. Similar PC are made for Article 800 sections and Article 820 sections.

Metallic conduit. Rigid metal conduit (RMC) or intermediate metal conduit (IMC), containing optical fiber entrance cable shall be connected by a bonding conductor or grounding electrode conductor to a grounding electrode in accordance with 770.100(B).

Statement of Problem and Substantiation for Public Comment

Section 770.49 is specific to metallic entrance conduit grounding. The only types of metallic entrance conduit permitted are RMC and IMC. Hence, in this section we are dealing only with RMC and IMC. While it is true that all metallic conduit should be grounded, such a general statement here may mislead the reader to incorrectly conclude that other types of metallic conduit may be used as entrance conduit.

### Committee Statement

- **Committee Action:** Accepted
- **Resolution:** SR-4514-NFPA 70-2015
- **Statement:** The addition of the wording “in accordance with 770.179” provides direction as to where the listing and marking requirements are located.
770.179 Optical Fiber Cables.

Optical fiber cables shall be listed, labeled and identified in accordance with 770.179(A) through (F) and shall be marked in accordance with Table 770.179. Optical fiber cables shall have a temperature rating of not less than 60°C (140°F). Temperature rating shall be marked on the jacket of optical fiber cables that have a temperature rating exceeding 60°C (140°F).

(A) Types OFNP and OFCP.

Types OFNP and OFCP nonconductive and conductive optical fiber plenum cables shall be listed as being suitable for use in ducts, plenums, and other space used for environmental air and shall also be listed as having adequate fire resistant and low smoke producing characteristics.

Informational Note: One method of defining a cable that is low-smoke producing cable and fire-resistant cable is that the cable exhibits a maximum peak optical density of 0.50 or less, an average optical density of 0.15 or less, and a maximum flame spread distance of 1.52 m (5 ft) or less when tested in accordance with NFPA 262-2015, Standard Method of Test for Flame Travel and Smoke of Wires and Cables for Use in Air-Handling Spaces.

(B) Types OFNR and OFCR.

Types OFNR and OFCR nonconductive and conductive optical fiber riser cables shall be listed as being suitable for use in a vertical run in a shaft or from floor to floor and shall also be listed as having the fire-resistant characteristics capable of preventing the carrying of fire from floor to floor.

Informational Note: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2011, Standard Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts.

(C) Types OFNG and OFCG.

Types OFNG and OFCG nonconductive and conductive general-purpose optical fiber cables shall be listed as being suitable for general-purpose use, with the exception of risers and plenums, and shall also be listed as being resistant to the spread of fire.

Informational Note: One method of defining resistant to the spread of fire is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA vertical flame test — cables in cable trays, as described in CSA C22.2 No. 0.3-M-2001, Test Methods for Electrical Wires and Cables.

Informational Note No. 1: One method of defining resistant to the spread of fire is that the cables do not spread fire to the top of the tray in the UL flame exposure, vertical tray flame test in ANSI/UL 1685-2010, Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables. The smoke measurements in the test method are not applicable.

Another method of defining resistant to the spread of fire is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA vertical flame test — cables in cable trays, as described in CSA C22.2 No. 0.3-M-2001, Test Methods for Electrical Wires and Cables.

Informational Note No. 2: Cable types are listed in descending order of fire resistance rating. Within each fire resistance rating, nonconductive cable is listed first because it may substitute for the conductive cable.

(E) Circuit Integrity (CI) Cable or Electrical Circuit Protective System.
Cables that are used for survivability of critical circuits under fire conditions shall be listed and meet either 770.179(E)(1) or (E)(2).

Informational Note: The listing organization provides information for circuit integrity (CI) cable and electrical circuit protective systems, including installation requirements necessary to maintain the fire rating.

(1) Circuit Integrity (CI) Cables.

Circuit integrity (CI) cables specified in 770.179(A) through (D), and used for survivability of critical circuits, shall have an additional classification using the suffix “CI.” In order to maintain its listed fire rating, circuit integrity (CI) cable shall only be installed in free air.

Informational Note: One method of defining circuit integrity (CI) cable is by establishing a minimum 2-hour fire resistance rating for the cable when tested in accordance with ANSI/UL 2196-2006, Standard for Tests of Fire-Resistive Cable.

(2) Fire-Resistive Cables.

Cables specified in 770.179(A) through (D) and 770.179(E)(1), that are part of an electrical circuit protective system, shall be fire-resistive cable and identified with the protective system number on the product or on the smallest unit container in which the product is packaged and installed in accordance with the listing of the protective system.

Informational Note No. 1: One method of defining an electrical circuit protective system is by establishing a minimum 2-hour fire resistance rating for the system when tested in accordance with UL Subject 1724, Outline of Investigation for Fire Tests for Electrical Circuit Protective Systems.

Informational Note No. 2: The listing organization provides information for electrical circuit protective systems (FHIT), including installation requirements for maintaining the fire rating.

(F) Field-Assembled Optical Fiber Cables.

Field-assembled optical fiber cable shall comply with 770.179(F)(1) through (4).

1) The specific combination of jacket and optical fibers intended to be installed as a field-assembled optical fiber cable shall be listed in accordance with one of the types identified by 770.179(A), (B), or (D) and shall be marked in accordance with Table 770.179.

2) The jacket of a field-assembled optical fiber cable shall have a surface marking indicating the specific optical fibers with which it is listed for, identified for use.

3) The optical fibers shall have a permanent marking, such as a marker tape, indicating the jacket with which they are listed for, identified for use.

4) The jacket without fibers shall meet the listing requirements for communications raceways in 800.182(A), (B), or (C) in accordance with the cable marking.

Additional Proposed Changes

<td></td>
</tr>
</tbody>
</table>
“original” certification of the product and indicates the authorization but not the mandate to label products. So the only true way an AHJ can determine whether the product he is seeing is compliant with the applicable standard is via a label on the product. Taking it one step further, listings change with time. It is quite possible that a “listing” has been withdrawn; however labeled product may still be available for sale. Should equipment that is labeled, but not listed, be deemed acceptable? Based on the NEC definitions, it is possible to have a product that meets the Article 100 definition of listed but the testing organization made the manufacture remove the label for a non-compliance issue.

As for the concerns of products that are too small to be labeled, the definition of labeled is not limited to an actual label, it also includes symbols, or other identifying marks. The Safety Standards which define the listing requirements do not address labeling of products as defined by Article 100. As a general rule, NRTL’s do not consider a product as being listed unless it is also labeled. The UL White Book states that “Only those products bearing the appropriate UL Mark and the company’s name, trade name, trademark or other authorized identification should be considered as being covered by UL’s Certification, Listing, Classification and Follow-Up Service. The UL Mark provides evidence of listing or labeling, which may be required by installation codes or standards.” Again the requirements for the UL Mark are not a Safety Standard requirement, they are a UL requirement and the only way to show that a product is UL Certified (Listed); other NRTL’s have similar requirements.

</tbody>
</table>
(B) Types OFNR and OFCR.

Types OFNR and OFCR nonconductive and conductive optical fiber riser cables shall be listed as being suitable for use in a vertical run in a shaft or from floor to floor and shall also be listed as having the fire-resistant characteristics capable of preventing the carrying of fire from floor to floor. Optionally, Types OFNR and OFCR riser cables shall be permitted to be marked as Type OFNR ST1 or OFCR ST1, respectively, if they are listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor and also listed as exhibiting limited smoke characteristics.

Informational Note 1: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2011, Standard Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts.

Informational Note 2: One method of defining optional limited smoke characteristics for riser cables is that the cables exhibit a peak smoke release rate not exceeding 0.40 m$^2$/s and a total smoke released not exceeding 150 m$^2$ when tested in accordance with the requirements of CSA "Vertical Flame Test - Cables in Cable Trays," as described in CSA C22.2 No. 0.3-M-2009, Test Methods for Wires and Cables.

Statement of Problem and Substantiation for Public Comment

Please reconsider the action on this public input and accept the public comment. Smoke obscuration is a key fire safety problem. The reason that this additional optional listing and informational note are important is that there is no information in any of the test methods for fire propagation of cables how to test for smoke in riser cables. Such information is neither included in UL 1666 nor in CSA FT4 nor in UL 1685. Therefore there can be no standardized way for a manufacturer to demonstrate that a specific type of riser cables has lower smoke than typical riser cables. This is very different from the case of general purpose (or cable tray) cables. Both UL 1685 and CSA FT4 contain information on how to obtain "limited smoke" (meaning reduced smoke) cables that are general purpose cables. Therefore I understand the panel's objections to include optional markings for these cables. However, unless the code provides a systematic and standard way to determine what is a "limited smoke riser cable" the optional markings will not be able to be generated adequately.

A key aspect of wire and cable fire performance is smoke emission since it is well known that lack of visibility and smoke are serious problems in fire. In the NEC there is a designation for "low smoke cables", which are plenum-rated cables. There is also an optional designation of limited smoke cables, which is not required but applies to cable tray cables (tested to UL 1685 or CSA FT4). Riser cables are cables that usually are found in concealed spaces and it would be important to offer an optional marking for limited smoke riser cables, to distinguish them from standard riser cables. This is particularly useful for riser cables because, typically, riser cables are made with insulation and jacket materials that are very similar to CSA FT4 cables and also with materials that do not quite exhibit the flame and smoke characteristics of plenum cables. Therefore, manufacturers of materials who try to achieve a plenum cable rating, and can't quite make it, will often make their material slightly less safe from the point of view of smoke emission, in order to be able to save costs. This new optional marking would permit manufacturers to provide cables with both limited smoke and the flame spread characteristics of riser cable. The choice of criterion for the limited smoke riser cables (and the choice of designation) is based on the ST1 designation associated with the CSA FT4 test, when smoke emission is assessed.

This public comment is being proposed for all instances of riser cables and not public comment is proposed for optional markings of general purpose cables.

Public Comment No. 181-NFPA 70-2015 [Section No. 800.1]

800.1  Scope.
This article covers communications circuits and equipment.

Informational Note No. 1: For further information for installations of communications circuits and equipment that are not covered.

Informational Note No. 2: For further information for remote-control, signaling, and power-limited circuits, see Article 725.

Informational Note No. 23: For further information for fire alarm systems, see Article 760.

Statement of Problem and Substantiation for Public Comment

Informational Note No. 1 referencing 90.2(B)(4) should not be deleted. It is extremely important, from a communications-provider point of view, that the reader and user of the Code be reminded that there are circumstances under which Article 800 does not apply. The presence of Informational Note No. 1 as contained in this Public Comment will help ensure that AHJs do not erroneously apply the requirements of Article 800 to facilities under the exclusive control of the communications utility.

Statement: Informational Note No. 1 referencing 90.2(B)(4) is not to be deleted. It is extremely important, from a communications-provider point of view, that the reader and user of the Code be reminded that there are circumstances under which Article 800 does not apply.
Exposed (to Accidental Contact).
A circuit that is in such a position that, in case of failure of supports or insulation, contact with another circuit may result.

Informational Note: See Part I of Article 100 for two other definitions of Exposed.

Statement of Problem and Substantiation for Public Comment

The Panel acted on PI 4562 to delete the Informational Note following 800.2, "Exposed (to Accidental Contact)" that passed ballot. This action is covered in FR 4512 that is not addressed in the First Draft Report. However, we do NOT agree that the Informational Note should be deleted. The term "Exposed" has multiple meanings throughout the NEC: uncovered and capable of being touched by persons, susceptible to physical damage, e.g., wiring attached to a surface, susceptible to power influences such as contact or induction, and susceptible to lightning influences, either a direct ‘hit’, induction or ground potential rise. Hence, the Informational Note provides clarity and should be maintained.

Public Comment No. 456-NFPA 70-2015 [ Definition: Point of Entrance. ]

Point of Entrance.
The point within a building at which the communications wire or cable emerges from an external wall, or from a concrete floor slab, from rigid metal conduit (RMC), or from intermediate metal conduit (IMC).

Statement of Problem and Substantiation for Public Comment

Panel action on FR 4654 for 800.48 added “The point of entrance shall be permitted to be extended from the penetration of the external wall or floor slab to the point of emergence from the rigid metal conduit (RMC) or intermediate metal conduit (IMC) by continuously enclosing the entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC).”

This action is confusing unless the definition of point of entrance is modified to remove the text about the point of entrance being the point where the cable emerges from the RMC or the IMC.

This PC is offered as an alternative to PC 457. Similar PC are made for Article 770 sections and Article 820 sections.

Public Comment No. 1872-NFPA 70-2015 [Section No. 800.3(F)]

(F) Premises-Powered Broadband Communications Systems.

Article 840 shall apply to premises-powered broadband communications systems. Part VI of Article 840 shall apply to communications equipment and cables that provide both power and communications signals to communications equipment.

Informational Note: Article 840 does not cover circuits such as those providing plain old telephone services (POTS) and similar legacy telecommunications services.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs that further consideration be given to the need for the revisions in 800.3(F) (excluding the addition of the Informational Note). The original sentence already points to the entire article and the additional sentence that points to Part VI is covered in that language. Further consideration should also be given to the need for the Informational Note.

Resolution: SR-4520-NFPA 70-2015
Statement: The second sentence is deleted to conform with NEC Style Manual Section 4.1.1.

The informational note does not provide additional clarity.
(G) Optical Fiber Cable. Where optical fiber cable is used, either in whole or in part, to provide a communications circuit within a building, Article 770 shall apply to the installation of the optical fiber portion of the communications circuit.

(H) Temperature Limitation of Conductors. Section 310.15(A)(3) shall apply.

Statement of Problem and Substantiation for Public Comment

CCCA submitted PI 193 to require temperature marking on cables for the obvious purpose of preventing the overheating of cables. Because Chapter 8 is independent, a reference to 310.15(A)(3) is needed. That section states:

(3) Temperature Limitation of Conductors. No conductor shall be used in such a manner that its operating temperature exceeds that designated for the type of insulated conductor involved. In no case shall conductors be associated together in such a way, with respect to type of circuit, the wiring method employed, or the number of conductors, that the limiting temperature of any conductor is exceeded.

Committee Action: Rejected but see related SR  
Resolution: SR-4523-NFPA 70-2015  
Statement: C2-2012 was approved by ANSI on June 3, 2011 and is referenced to IEEE. The 2017 edition of the NESC has not yet been adopted.
Underground communications wires and cables entering buildings shall comply with 800.47(A) and (B). The requirements of 310.10(C) shall not apply to communications wires and cables.

**Statement of Problem and Substantiation for Public Comment**

I reach out to the inspector members article 800 which is intended to be a stand alone article and not be associated with other articles such as 725 and others. As you define Communication as "the circuit that extends voice, video, data, interactive services, telegraph, outside wiring for "fire alarm and burglar alarm from the communication utility to the "customers communications equipment up to and including terminal equipment. Try and explain to a contractor what this does and does not include. Actually being an inspector for 15 years I personally cannot distinguish the difference from communication circuits which is a class 2 and 3 supply and what only is a circuit from NEC 725. I do know that data is more and more important as the codes reflect. Not requiring a wet location listing because Belden doesn't list theirs appears to be a lapse in judgment. Please reconsider

Communication wires can be as important if not more important for the safe guarding of persons and property that line voltage. In today's world of technology it is so obvious that communication cables carry critical information and needs to be protected. The language that was added in the 2011 was to exclude the wiring from having to have a "wet location" listing. I would hope that the committee would listen to an electrical inspector for 14 years in stating that this was an ill advised change with compounding consequences. Reading the scope of article 800 Communication is a very broad area. In the definitions for Communication Circuit = the circuit that extends voice, audio, video, data, interactive services, outside wiring for fire alarm and burglar alarm from the communication utility to the customers communication equipment up to and including terminal equipment such as telephone, fax or answering machine. With today's technology, state of the art equipment is very dependent on low voltage communication circuits. Health care is so concerned about the communication rooms that they are treated like an island, NFPA 99 mandates that no other piping can be located under the slab or ran through the room unless it is terminated for that room. Data centers that control the worlds financing, electrical grid ,water , gas and oil piping is all communicated with low voltage communication wiring.

As a code making panel member you can try to justify that fire alarm and other low volt systems have their own article, but I am here to state with certainty that article 800 can be argued for all these cables and to justify not having to install 'wet location cable” Removing the language for the 2017 code that was inserted in 2011 will give all manufacturers plenty of time to have their cables listed for a wet location. If you were to question 100 active electricians and asked them to identify the cable going from a UPS or information technology room they would reply a communication cable” Low voltage cables is too important in today's industry to have this language excluding the requirements for the cable to be listed “wet location”. I inspect data centers that control finances, satellite dishes that control much more than your tv, hospitals that communicate blood type and water treatment plants that rely on data. When 800.47 inserted the words 310.10(C) shall not apply installers have taken that as a free pass. Please correct this wrong. This same code panel felt justified to insert “circuit integrity cables” into this article. It appears troublesome to have the original proposal stating that because they did not have a cable listed for wet location there should be an exception for it. Best Regards, I do have actual data of cables failing because of water immersion in a pipe underground and causing major down time for satellite dishes communications on a very large level. Feel free to contact me for specifics.

800.48 Unlisted Cables Entering Buildings.

Unlisted outside plant communications cables shall be permitted to be installed in building spaces other than risers, ducts used for environmental air, plenums used for environmental air, and other spaces used for environmental air, where the length of the cable within the building, measured from its point of entrance, does not exceed 15 m (50 ft) and the cable enters the building from the outside and is terminated in an enclosure or on a listed primary protector. The point of entrance shall be permitted to be extended from the penetration of the external wall or floor slab to the point of emergence from the rigid metal conduit (RMC) or intermediate metal conduit (IMC) by continuously enclosing the entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC).

Informational Note No. 1: Splice cases or terminal boxes, both metallic and plastic types, are typically used as enclosures for splicing or terminating telephone cables.

Informational Note No. 2: This section limits the length of unlisted outside plant cable to 15 m (50 ft), while 800.90(B) requires that the primary protector be located as close as practicable to the point at which the cable enters the building. Therefore, in installations requiring a primary protector, the outside plant cable may not be permitted to extend 15 m (50 ft) into the building if it is practicable to place the primary protector closer than 15 m (50 ft) to the point of entrance.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs that further consideration be given to the comments expressed in voting on FR 4654.

Resolution: SR-4524-NFPA 70-2015
Statement: The text is appropriate as a requirement. According to the NEC Style Manual Section 3.1.3, informational notes shall not be written in mandatory language and shall not contain requirements, make interpretations, or make recommendations. The proposed informational Note 3 is superfluous based on changes made to the mandatory text.

This second revision reflects the CC concerns on the ballot comments and PC-190 concerns regarding the committee statement for FR-4654.
800.48 Unlisted Cables Entering Buildings.

Unlisted outside plant communications cables shall be permitted to be installed in building spaces other than risers, ducts used for environmental air, plenums used for environmental air, and other spaces used for environmental air, where the length of the cable within the building, measured from its point of entrance, does not exceed 15 m (50 ft) and the cable enters the building from the outside and is terminated in an enclosure or on a listed primary protector. The point of entrance shall be permitted to be extended from the penetration of the external wall or floor slab to the point of emergence from the rigid metal conduit (RMC) or intermediate metal conduit (IMC) by continuously enclosing the entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC).

Informational Note No. 1: Splice cases or terminal boxes, both metallic and plastic types, are typically used as enclosures for splicing or terminating telephone cables.

Informational Note No. 2: This section limits the length of unlisted outside plant cable to 15 m (50 ft), while 800.90(B) requires that the primary protector be located as close as practicable to the point at which the cable enters the building. Therefore, in installations requiring a primary protector, the outside plant cable may not be permitted to extend 15 m (50 ft) into the building if it is practicable to place the primary protector closer than 15 m (50 ft) to the point of entrance.

Informational Note No. 3: The point of entrance may be extended further into the building by continuing to enclose the entrance cable in rigid metal conduit (RMC) or intermediate metal conduit (IMC).

Statement of Problem and Substantiation for Public Comment

The proposed added text “The point of entrance shall be permitted to be extended from the penetration of the external wall or floor slab to the point of emergence from the rigid metal conduit (RMC) or intermediate metal conduit (IMC) by continuously enclosing the entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC)” is a cumbersome and run-on sentence that is both confusing and redundant. The definition, “point of entrance”, currently and adequately defines RMC and IMC as acceptable vehicles establishing the point of entrance. If the Panel feels it is necessary to further clarify the use of RMC and IMC, greater clarity is provided by a simple Informational Note.

Submittal Date: Thu Jul 09 09:02:42 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4524-NFPA 70-2015
Statement: The text is appropriate as a requirement. According to the NEC Style Manual Section 3.1.3, informational notes shall not be written in mandatory language and shall not contain requirements, make interpretations, or make recommendations. The proposed informational Note 3 is superfluous based on changes made to the mandatory text.

This second revision reflects the CC concerns on the ballot comments and PC-190 concerns regarding the committee statement for FR-4654.
800.48  Unlisted Cables Entering Buildings.

Unlisted outside plant communications cables shall be permitted to be installed in building spaces other than risers, ducts used for environmental air, plenums used for environmental air, and other spaces used for environmental air, where the length of the cable within the building, measured from its point of entrance, does not exceed 15 m (50 ft) and the cable enters the building from the outside and is terminated in an enclosure or on a listed primary protector. The point of entrance shall be permitted to be extended from the penetration of the external wall or floor slab to the point of emergence from the rigid metal conduit (RMC) or intermediate metal conduit (IMC) by continuously enclosing the entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC).

Informational Note No. 1: Splice cases or terminal boxes, both metallic and plastic types, are typically used as enclosures for splicing or terminating telephone cables.

Informational Note No. 2: This section limits the length of unlisted outside plant cable to 15 m (50 ft), while 800.90(B) requires that the primary protector be located as close as practicable to the point at which the cable enters the building. Therefore, in installations requiring a primary protector, the outside plant cable may not be permitted to extend 15 m (50 ft) into the building if it is practicable to place the primary protector closer than 15 m (50 ft) to the point of entrance.

Statement of Problem and Substantiation for Public Comment

FR 4654 and the First Draft Report text doesn’t agree with the Committee Statement. There is no text providing clarification that rigid polyvinyl chloride conduit and electrical metallic tubing containing unlisted outside plant cable are not permitted to be installed in risers, air ducts or plenums.

The proposed Informational Note 3 is superfluous based on changes made to the mandatory text.

This second revision reflects the CC concerns on the ballot comments and PC-190 concerns regarding the committee statement for FR-4654.
800.48 Unlisted Cables Entering Buildings.

Unlisted outside plant communications cables shall be permitted to be installed in building spaces other than risers, ducts used for environmental air, plenums used for environmental air, and other spaces used for environmental air, where the length of the cable within the building, measured from its point of entrance, does not exceed 15 m (50 ft) and the cable enters the building from the outside and is terminated in an enclosure or on a listed primary protector. The point of entrance shall be permitted to be extended from the penetration of the external wall or floor slab to the point of emergence from the rigid metal conduit (RMC) or intermediate metal conduit (IMC) by continuously enclosing the entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC).

Informational Note No. 1: Splice cases or terminal boxes, both metallic and plastic types, are typically used as enclosures for splicing or terminating telephone cables.

Informational Note No. 2: This section limits the length of unlisted outside plant cable to 15 m (50 ft), while 800.90(B) requires that the primary protector be located as close as practicable to the point at which the cable enters the building. Therefore, in installations requiring a primary protector, the outside plant cable may not be permitted to extend 15 m (50 ft) into the building if it is practicable to place the primary protector closer than 15 m (50 ft) to the point of entrance.

Informational Note No. 3: Continuously enclosing entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC) extends the point of entrance from penetration of the external wall or floor slab to the point of emergence from the rigid metal conduit (RMC) or intermediate metal conduit (IMC).

Statement of Problem and Substantiation for Public Comment

The added text about extending the point of entrance was recommended to be an informational note in PI 1566. If the panel had adopted that recommendation, it would have avoided the confusion of permitting the extension of the point of entrance by using RMC or IMC when the point of entrance is already defined as the point emergence from RMC or IMC.

This PC is offered as an alternative to PC 456. Similar PC are made for Article 770 sections and Article 820 sections.

Statement: The text is appropriate as a requirement. According to the NEC Style Manual Section 3.1.3, informational notes shall not be written in mandatory language and shall not contain requirements, make interpretations, or make recommendations. The proposed informational Note 3 is superfluous based on changes made to the mandatory text.

This second revision reflects the CC concerns on the ballot comments and PC-190 concerns regarding the committee statement for FR-4654.
800.49 Metallic Entrance Conduit Grounding.

Metallic conduit containing Rigid metal conduit (RMC) or intermediate metal conduit (IMC) containing communications entrance wire or cable shall be connected by a bonding conductor or grounding electrode conductor to a grounding electrode in accordance with 800.100(B).

Statement of Problem and Substantiation for Public Comment

Section 800.49 is specific to metallic entrance conduit grounding. The only types of metallic entrance conduit permitted are RMC and IMC. Hence, in this section we are dealing only with RMC and IMC. While it is true that all metallic conduit should be grounded, such a general statement here may mislead the reader to incorrectly conclude that other types of metallic conduit may be used as entrance conduit.

Committee Statement

Committee Action: Rejected
Resolution: Other types of metal conduit besides RMC and IMC are permitted to be used as entrance conduit. All metal conduit is required to be bonded and grounded.
Public Comment No. 50-NFPA 70-2015 [Section No. 800.90(A)]

(A) Application.
A listed primary protector shall be provided on each circuit run partly or entirely in aerial wire or aerial cable not confined within a block. Also, a listed primary protector shall be provided on each circuit, aerial or underground, located within the block containing the building served so as to be exposed to accidental contact with electric light or power conductors operating at over 300 volts to ground. In addition, where there exists a lightning exposure, each interbuilding circuit on a premises shall be protected by a listed primary protector at each end of the interbuilding circuit. Installation of primary protectors shall also comply with 110.3(B).

Informational Note No. 1: On a circuit not exposed to accidental contact with power conductors, providing a listed primary protector in accordance with this article helps protect against other hazards, such as lightning and above-normal voltages induced by fault currents on power circuits in proximity to the communications circuit.

Informational Note No. 2: Interbuilding circuits are considered to have a lightning exposure unless one or more of the following conditions exist:

1. Circuits in large metropolitan areas where buildings are close together and sufficiently high to intercept lightning.
2. Interbuilding cable runs of 42 m (140 ft) or less, directly buried or in underground conduit, where a continuous metallic cable shield or a continuous metallic conduit containing the cable is connected to each building grounding electrode system.
3. Areas having an average of five or fewer thunderstorm days per year and earth resistivity of less than 100 ohm-meters. Such areas are found along the Pacific coast.

Informational Note: For information on lightning protection systems, see NFPA 780-2014, Standard for the Installation of Lightning Protection Systems.

(i) Fuseless Primary Protectors.
Fuseless-type primary protectors shall be permitted under any of the conditions given in (A)(1)(a) through (A)(1)(e).

(a) Where conductors enter a building through a cable with grounded metallic sheath member(s) and where the conductors in the cable safety fuse on all currents greater than the current-carrying capacity of the primary protector and of the primary protector bonding conductor or grounding electrode conductor

(b) Where insulated conductors in accordance with 800.50(A) are used to extend circuits to a building from a cable with an effectively grounded metallic sheath member(s) and where the conductors in the cable or cable stub, or the connections between the insulated conductors and the plant exposed to accidental contact with electric light or power conductors operating at greater than 300 volts to ground, safety fuse on all currents greater than the current-carrying capacity of the primary protector, or the associated insulated conductors and of the primary protector bonding conductor or grounding electrode conductor

(c) Where insulated conductors in accordance with 800.50(A) or (B) are used to extend circuits to a building from other than a cable with metallic sheath member(s), where (1) the primary protector is listed as being suitable for this purpose for application with circuits extending from other than a cable with metallic sheath members, and (2) the connections of the insulated conductors to the plant exposed to accidental contact with electric light or power conductors operating at greater than 300 volts to ground or the conductors of the plant exposed to accidental contact with electric light or power conductors operating at greater than 300 volts to ground safety fuse on all currents greater than the current-carrying capacity of the primary protector, or associated insulated conductors and of the primary protector bonding conductor or grounding electrode conductor

(d) Where insulated conductors in accordance with 800.50(A) are used to extend circuits to a building from a buried or underground circuit that is unexposed to accidental contact with electric light or power conductors operating at greater than 300 volts to ground

(e) Where insulated conductors in accordance with 800.50(A) are used to extend circuits to a building from cable with an effectively grounded metallic sheath member(s), and where (1) the combination of the primary protector and insulated conductors is listed as being suitable for this purpose for application with circuits extending from a cable with an effectively grounded metallic sheath member(s), and (2) the insulated conductors safety fuse on all currents greater than the current-carrying capacity of the primary protector and of the primary protector bonding conductor or grounding electrode conductor

Informational Note: Section 9 of ANSI of IEEE, C2-2012, National Electrical Safety Code, provides an example of methods of protective grounding that can achieve effective grounding of communications cable sheaths for cables from which communications circuits are extended.

(2) Fused Primary Protectors.
Where the requirements listed under 800.90(A)(1) (a) through (A)(1)(e) are not met, fused-type primary protectors shall be used. Fused-type primary protectors shall consist of an arrester connected between each line conductor and ground, a fuse in series with each line conductor, and an appropriate mounting arrangement. Primary protector terminals shall be marked to indicate line, instrument, and ground, as applicable.
Referenced correct SDO in informational note for (1) (e).

(C) Other Spaces Used for Environmental Air (Plenums).

The following wires, cables, raceways, and cable routing assemblies shall be permitted in other spaces used for environmental air as described in 300.22(C):

1. Type CMP cables
2. Plenum communications raceways
3. Plenum cable routing assemblies
4. Type CMP cables installed in plenum communications raceways
5. Type CMP cables installed in plenum cable routing assemblies
6. Type CMP cables and plenum communications raceways supported by open metallic cable trays or cable tray systems
7. Types CMP, CMR, CMG, CM, and CMX cables and communications wires installed in raceways that are installed in compliance with 300.22(C)
8. Types CMP, CMR, CMG, CM, and CMX cables, plenum communications raceways, riser communications raceways, and general-purpose communications raceways supported by solid bottom metal cable trays with solid metal covers in other spaces used for environmental air (plenums) as described in 300.22(C)
9. Types CMP, CMR, CMG, CM, and CMX cables installed in plenum communications raceways, riser communications raceways, and general-purpose communications raceways supported by solid bottom metal cable trays with solid metal covers in other spaces used for environmental air (plenums) as described in 300.22(C)

Informational Note: For information on fire protection of wiring installed in other spaces used for environmental air, see 4.3.11.2, 4.3.11.4, and 4.3.11.5 of NFPA 90A-2015, Standard for the Installation of Air-Conditioning and Ventilating Systems.

Statement of Problem and Substantiation for Public Comment

Committee Statement

Committee Action: Rejected
Resolution: While the exact text “used as innerduct” is not incorporated in the title, the First Revision text meets the objective of addressing cables and innerduct in metallic raceways. Hence, no text change is necessary to 800.113(E) title.
Other Building Locations.

The following wires, cables, raceways, and cable routing assemblies shall be permitted to be installed in building locations other than the locations covered in 800.113(B) through (I):

1. Types CMP, CMR, CMG, and CM cables

2. A maximum of 3 m (10 ft) of exposed Type CMX in nonconcealed spaces

3. Plenum, riser, and general-purpose communications raceways

4. Plenum, riser, and general-purpose cable routing assemblies

5. Communications wires and Types CMP, CMR, CMG, and CM cables installed in:
   6. Plenum communications raceways
   7. Riser communications raceways
   8. General-purpose communications raceways

9. Types CMP, CMR, CMG, and CM cables installed in:
   10. Plenum cable routing assemblies
   11. Riser cable routing assemblies
   12. General-purpose cable routing assemblies

13. Communications wires and Types CMP, CMR, CMG, CM, and CMX cables installed in raceways recognized in Chapter 3

14. Type CMUC under-carpet communications wires and cables installed under carpet, or under floor covering, modular tiles, flooring, and planks.

Statement of Problem and Substantiation for Public Comment

This Public Comment is an editorial clarification. The submitter of PI 2616 also submitted PI 2623 to change the name of Type CMUC from “Undercarpet communications wire and cable” to “Under-floor Covering communications wire and cable”. CMP-16 resolved PI 2623 with the statement: “There is no need to change the section title and table and alter the listing requirements in order to accommodate the use of these cables under modular flooring and planks.”

The wording of the Resolution statement for PI 2623 is clear that the intent is to permit installation “under modular flooring and planks” in addition to installation under carpet. Accordingly, this Public Comment recommends text that permits the installation of Type CMUC “under carpet, modular flooring and planks.”

Note that this input has apparently been afflicted with the random underlining bug in the TerraWare software, and is not within the control of the submitter. This comment only deals with the installation of Type CMUC.

One- and Two-Family Dwellings.

The following cables, raceways, and cable routing assemblies shall be permitted to be installed in one- and two-family dwellings in locations other than the locations covered in 800.113(B) through 800.113(F):

1. Types CMP, CMR, CMG, and CM cables
2. Type CMX cables less than 6 mm (0.25 in.) in diameter
3. Plenum, riser, and general-purpose communications raceways
4. Plenum, riser, and general-purpose cable routing assemblies
5. Communications wires and Types CMP, CMR, CMG, and CM cables installed in:
   6. Plenum communications raceways
   7. Riser communications raceways
   8. General-purpose communications raceways
9. Types CMP, CMR, CMG, and CM cables installed in:
   10. Plenum cable routing assemblies
    11. Riser cable routing assemblies
    12. General-purpose cable routing assemblies
13. Communications wires and Types CMP, CMR, CMG, CM, and CMX cables installed in raceways recognized in Chapter 3
14. Type CMUC under-carpet communications wires and cables installed under carpet, modular tiles, flooring, and planks
15. Hybrid power and communications cable listed in accordance with 800.179(I)

Statement of Problem and Substantiation for Public Comment

This Public Comment is an editorial clarification. The submitter of PI 2616 also submitted PI 2623 to change the name of Type CMUC from “Undercarpet communications wire and cable” to “Under-floor Covering communications wire and cable”. CMP-16 resolved PI 2623 with the statement: “There is no need to change the section title and table and alter the listing requirements in order to accommodate the use of these cables under modular flooring and planks.”

The wording of the Resolution statement for PI 2623 is clear that the intent is to permit installation “under modular flooring and planks” in addition to installation under carpet. Accordingly, this Public Comment recommends text that permits the installation of Type CMUC “under carpet, modular flooring and planks”.

Note that this input has apparently been afflicted with the random underlining bug in the TerraWare software, and is not within the control of the submitter. This comment only deals with the installation of Type CMUC.

Public Comment No. 378-NFPA 70-2015 [Section No. 800.133(A)(1)]

(1) In Raceways, Cable Trays, Boxes, Cables, Enclosures, and Cable Routing Assemblies.
(a) Optical Fiber and Communications Cables. Communications cables shall be permitted in the same raceway, cable tray, box, enclosure, or cable routing assembly with cables of any of the following:
- Nonconductive and conductive optical fiber cables in compliance with Parts I and V of Article 770
- Community antenna television and radio distribution systems in compliance with Parts I and V of Article 820
- Low-power network-powered broadband communications circuits in compliance with Parts I and V of Article 830
(b) Other Circuits. Communications cables shall be permitted in the same raceway, cable tray, box, enclosure, or cable routing assembly with cables of any of the following:
1. Class 2 and Class 3 remote-control, signaling, and power-limited circuits in compliance with Article 645 or Parts I and III of Article 725
2. Power-limited fire alarm systems in compliance with Parts I and III of Article 760
3. Nonconductive and conductive optical fiber cables in compliance with Parts I and V of Article 770
4. Community antenna television and radio distribution systems in compliance with Parts I and V of Article 820
5. Low-power network-powered broadband communications circuits in compliance with Parts I and V of Article 830
(c) Class 2 and Class 3 Circuits. Class 1 circuits shall not be run in the same cable with communications circuits. Class 2 and Class 3 circuit conductors shall be permitted in the same cable with communications circuits, in which case the Class 2 and Class 3 circuits shall be classified as communications circuits and shall meet the requirements of this article. The cables shall be listed as communications cables.

Exception: Cables constructed of individually listed Class 2, Class 3, and communications cables under a common jacket shall not be required to be classified as communications cable. The fire-resistance rating of the composite cable shall be determined by the performance of the composite cable.
(d) Electric Light, Power, Class 1, Non–Power-Limited Fire Alarm, and Medium-Power Network-Powered Broadband Communications in Raceways, Compartment, and Boxes. Communications conductors shall not be placed in any raceway, compartment, outlet box, junction box, or similar fittings with conductors of electric light, power, Class 1, non–power-limited fire alarm, or medium-power network-powered broadband communications circuits.

Exception No. 1: Section 800.133(A)(1) shall not apply if all of the conductors of electric light, power, Class 1, non–power-limited fire alarm, and medium-power network-powered broadband communications circuits are separated from all of the conductors of communications circuits by a permanent barrier or listed divider.

Exception No. 2: Power conductors in outlet boxes, junction boxes, or similar fittings or compartments where such conductors are introduced solely for power supply to communications equipment. The power circuit conductors shall be routed within the enclosure to maintain a minimum of 6 mm (1/4 in.) separation from the communications circuit conductors.

Exception No. 3: As permitted by 620.36.

Statement of Problem and Substantiation for Public Comment

This section was separated into two parts in the 2011 NEC because cable routing assemblies were not recognized in Articles 725 and 760. Now that there are consistent provisions for cable routing assemblies in Articles 725, 760, 800, 820 & 830, it is no longer necessary to subdivide the section. CMP 16 created similar First Revisions in Articles 770 (FR 4540), 820 (FR4578) and 830 (FR4645).

This Public Comment basically recommends acceptance of PI 190.

800.154 Applications of Listed Communications Wires, Cables and Raceways, and Listed Cable Routing Assemblies.
Permitted and nonpermitted applications of listed communications wires, cables, and raceways, and listed cable routing assemblies, shall be in accordance with one of the following:

1. Listed communications wires and cables as indicated in Table 800.154(a)
2. Listed communications raceways as indicated in Table 800.154(b)
3. Listed cable routing assemblies as indicated in Table 800.154(c)

The permitted applications shall be subject to the installation requirements of 800.110 and 800.113. The substitutions for communications cables listed in Table 800.154(d) and illustrated in Figure 800.154 shall be permitted.

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-4535-NFPA 70-2015
Statement: The sentence "The definition of Point of Entrance is in 800.2." of Informational Note No. 1 to Table 800.154(a) was incorrectly deleted in the First Revision. It is only the third sentence that should be deleted as indicated in the Committee Statement to FR 4676 where it is stated: "It is sufficient that Informational Note No. 1 direct the reader to the definition in 800.2 thus avoiding potential confusion."
Applications of Listed Communications Wires, Cables and Raceways, and Listed Cable Routing Assemblies.
Permitted and nonpermitted applications of listed communications wires, cables, and raceways, and listed cable routing assemblies, shall be in accordance with one of the following:

1. Listed communications wires and cables as indicated in Table 800.154(a)
2. Listed communications raceways as indicated in Table 800.154(b)
3. Listed cable routing assemblies as indicated in Table 800.154(c)

The permitted applications shall be subject to the installation requirements of 800.110 and 800.113. The substitutions for communications cables listed in Table 800.154(d) and illustrated in Figure 800.154 shall be permitted.

Statement of Problem and Substantiation for Public Comment

The sentence "The definition of Point of Entrance is in 800.2." of IN No. 1 to Table 800.154(a) is incorrectly deleted. It is only the third sentence that should be deleted as indicated in the Committee Statement to FR 4676 where it is stated: "It is sufficient that IN No. 1 direct the reader to the definition in 800.2 thus avoiding potential confusion." The Committee Statement to FR 4676 also states that Informational Note No. 2 has been revised. The First Draft Report text for Informational Note No. 2 does not reflect any changes as it is identical to the NEC, 2014 Edition.

Committee Statement

Rejected but see related SR
The sentence "The definition of Point of Entrance is in 800.2." of Informational Note No. 1 to Table 800.154(a) was incorrectly deleted in the First Revision. It is only the third sentence that should be deleted as indicated in the Committee Statement to FR 4676 where it is stated: "It is sufficient that Informational Note No. 1 direct the reader to the definition in 800.2 thus avoiding potential confusion."
800.154 Applications of Listed Communications Wires, Cables and Raceways, and Listed Cable Routing Assemblies.
Permitted and nonpermitted applications of listed communications wires, cables, and raceways, and listed cable routing assemblies, shall be in accordance with one of the following:

(1) Listed communications wires and cables as indicated in Table 800.154(a)

(2) Listed communications raceways as indicated in Table 800.154(b)

(3) Listed cable routing assemblies as indicated in Table 800.154(c)

The permitted applications shall be subject to the installation requirements of 800.110 and 800.113. The substitutions for communications cables listed in Table 800.154(d) and illustrated in Figure 800.154 shall be permitted. Cables with additional listings that are marked with a suffix shall be permitted to substitute for the basic cable without the suffix. For example, Type CMR-CI is permitted to substitute for Type CMR and Type CMP-LP is permitted to substitute for Type CMP-LP.

Figure 800.154 Cable Substitution Hierarchy.

Statement of Problem and Substantiation for Public Comment

Explicitly permitting cables with a suffix such as Type CMR-CI and Type CMR-LP to substitute for the basic Type CMR adds clarity. While it may be obvious to most members of CMP-16 that these substitutions are permitted, some members of CMP-3 do not necessarily agree. Since CMP-3 permits communications cables to substitute for Class 2 and Class 3 cables in Article 725, adding the recommended clarifying text will help in the correlation of Article 800 with Article 725.

Resolution: Existing requirements already allow cable substitution. The proposed text does not provide any additional clarification.
Public Comment No. 209-NFPA 70-2015 [Section No. 800.170]

800.170. Equipment.
Communications equipment shall be listed as being suitable for electrical connection to a communications network.

(A) Primary Protectors.
The primary protector shall consist of an arrester connected between each line conductor and ground in an appropriate mounting. Primary protector terminals shall be marked to indicate line and ground as applicable.

Informational Note: One way to determine applicable requirements for a listed primary protector is to refer to ANSI/UL 497-2012, Standard for Protectors for Paired Conductor Communications Circuits.

(B) Secondary Protectors.
The secondary protector shall be listed as suitable to provide means to safely limit currents to less than the current-carrying capacity of listed indoor communications wire and cable, listed telephone set line cords, and listed communications terminal equipment having ports for external wire line communications circuits. Any overvoltage protection, arresters, or grounding connection shall be connected on the equipment terminals side of the secondary protector current-limiting means.

Informational Note: One way to determine applicable requirements for a listed secondary protector is to refer to ANSI/UL 497A-2012, Standard for Secondary Protectors for Communications Circuits.

(C) Plenum Grade Cable Ties.
Cable ties intended for use in other space used for environmental air (plenums) shall be listed as having low smoke and heat release properties.

Resolution: SR-4536-NFPA 70-2015
Statement: Referenced UL documents are updated to the current issue and reference to ANSI has been added as applicable.
(B) Type CMR.

Type CMR communications riser cables shall be listed as being suitable for use in a vertical run in a shaft or from floor to floor and shall also be listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor. Optionally, Type CMR riser cables shall be permitted to be marked as Type CMR ST1 if they are listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor and also listed as exhibiting limited smoke characteristics.

Informational Note 1: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2011, Standard Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts.

Informational Note 2: One method of defining optional limited smoke characteristics for riser cables is that the cables exhibit a peak smoke release rate not exceeding 0.40 m²/s and a total smoke released not exceeding 150 m² when tested in accordance with the requirements of CSA, "Vertical Flame Test - Cables in Cable Trays," as described in CSA C22.2 No. 0.3-M-2009, Test Methods for Wires and Cables.

Statement of Problem and Substantiation for Public Comment

Please reconsider the action on this public input and accept the public comment. Smoke obscuration is a key fire safety problem.

The reason that this additional optional listing and informational note are important is that there is no information in any of the test methods for fire propagation of cables how to test for smoke in riser cables. Such information is neither included in UL 1666 nor in CSA FT4 nor in UL 1685. Therefore there can be no standardized way for a manufacturer to demonstrate that a specific type of riser cables has lower smoke than typical riser cables. This is very different from the case of general purpose (or cable tray) cables. Both UL 1685 and CSA FT4 contain information on how to obtain "limited smoke" (meaning reduced smoke) cables that are general purpose cables. Therefore I understand the panel's objections to include optional markings for these cables. However, unless the code provides a systematic and standard way to determine what is a "limited smoke riser cable" the optional markings will not be able to be generated adequately.

A key aspect of wire and cable fire performance is smoke emission since it is well known that lack of visibility and smoke are serious problems in fire. In the NEC there is a designation for "low smoke cables", which are plenum-rated cables. There is also an optional designation of limited smoke cables, which is not required but applies to cable tray cables (tested to UL 1685 or CSA FT4). Riser cables are cables that usually are found in concealed spaces and it would be important to offer an optional marking for limited smoke riser cables, to distinguish them from standard riser cables. This is particularly useful for riser cables because, typically, riser cables are made with insulation and jacket materials that are very similar to CSA FT4 cables and also with materials that do not quite exhibit the smoke characteristics of plenum cables. Therefore, manufacturers of materials who try to achieve a plenum cable rating, and can't quite make it, will often make their material slightly less safe from the point of view of smoke emission, in order to be able to save costs. This new optional marking would permit manufacturers to provide cables with both limited smoke and the flame spread characteristics of riser cable. The choice of criterion for the limited smoke riser cables (and the choice of designation) is based on the ST1 designation associated with the CSA FT4 test, when smoke emission is assessed.

This public comment is being proposed for all instances of riser cables and not public comment is proposed for optional markings of general purpose cables.

Public Comment No. 1876-NFPA 70-2015 [Section No. 800.182(A)]

(A) Cable Routing Assemblies and Plenum Communications Raceways.

Plenum cable routing assemblies and plenum communications raceways shall be listed as having adequate fire-resistant and low-smoke producing characteristics.

Informational Note No. 1: One method of defining cable routing assemblies and communications raceways that have adequate fire-resistant and low-smoke producing characteristics is that they exhibit a maximum flame spread index of 25 and a maximum smoke developed index of 50 when tested in accordance with ASTM E84-2014, Standard Test Method for Surface Burning Characteristics of Building Materials, or ANSI/UL 723-2013, Standard Test Method for Surface Burning Characteristics of Building Materials.

Informational Note No. 2: Another method of defining communications raceways that have adequate fire-resistant and low-smoke producing characteristics is that they exhibit a maximum peak optical density of 0.50 or less, an average optical density of 0.15 or less, and a maximum flame spread distance of 1.52 m (5 ft) or less when tested in accordance with NFPA 262-2015, Standard Method of Test for Flame Travel and Smoke of Wires and Cables for Use in Air-Handling Spaces.

Informational Note No. 3: See 4.3.11.2.6 or 4.3.11.5.5 of NFPA 90A-2015, Standard for the Installation of Air-Conditioning and Ventilating Systems, for information on materials exposed to the airflow in ceiling cavity and raised floor plenums.

Statement of Problem and Substantiation for Public Comment

The title should be "(A) Plenum Cable Routing Assemblies and Plenum Communications Raceways" for consistency with the first paragraph. The word "plenum" prior to "Cable Routing Assemblies" was omitted.

810.6  Antenna Lead-In Protectors.

Where an antenna lead-in surge protector is installed, it shall be listed as being suitable for limiting surges on the cable that connects the antenna to the receiver/transmitter electronics and shall be connected between the conductors and the grounded shield or other ground connection. The antenna lead-in protector shall be grounded using a bonding conductor or grounding electrode conductor installed in accordance with 810.21(F).

Informational Note: For requirements covering protectors for antenna lead-in conductors, refer to UL Subject 497E Outline, Outline of Investigation for Protectors for Antenna Lead-In Conductors.

Statement of Problem and Substantiation for Public Comment

Committee Statement

Committee Action: Accepted
Resolution: SR-4538-NFPA 70-2015
Statement: The informational note is revised to reflect the current title of UL 479E as “UL 479 E Outline, Outline of Investigation for Protectors for Antenna Lead-In Conductors”.
**Public Comment No. 322-NFPA 70-2015 [Section No. 810.15]**

810.15  **Grounding.**
Masts and metal structures supporting antennas shall be grounded in accordance with 810.21, unless the antenna and its related supporting mast or structure are within a zone of protection defined by a 46 m (150 ft) radius rolling sphere.

Informational Note: See NFPA 780-2014, *Standard for the Installation of Lightning Protection Systems*, 4.8.3.1 for the theory, the application, of the term “rolling sphere.”

**Statement of Problem and Substantiation for Public Comment**

The use of the word "theory" is misleading because this word implies that a technical study has been performed where mathematical equations are involved. Instead the correct word to be used is "application" because this method was developed based on field applications.

**Committee Statement**

Committee Action: Accepted  
Resolution: SR-4539-NFPA 70-2015  
Statement: Use of the word “application” clarifies the intended purpose of the informational note.
810.15  Grounding.

Masts and metal structures supporting antennas shall be grounded, bonded, in accordance with 810.21, unless the antenna and its related supporting mast or structure are within a zone of protection defined by a 46 m (150 ft) radius rolling sphere.

Informational Note: See NFPA 780-2014, Standard for the Installation of Lightning Protection Systems, 4.8.3.1 for the theory of the term “rolling sphere.”

Statement of Problem and Substantiation for Public Comment

Delete added text for two reasons: (1) does the Code panel really think that the reader of the Code is going to get NFPA 780, learn about lightning protection and the zone of protection? (2) 'bonding' of the metal antenna per 810.21 (which is what we are doing), so change grounding to bonding.

Committee Statement

Committee Action: Rejected
Resolutions: Masts and metal structures supporting antennas, unless within a “zone of protection”, must be grounded to a grounding electrode or grounding electrode system via a grounding electrode conductor. Hence, “grounding” is the correct term. The supporting mast or metal structure may also be bonded to nearby metallic structures via a bonding conductor to prevent arcing and potential electric shock hazard during lightning events. Section 810.21 addresses both bonding conductors and grounding electrode conductors. If the reader of the Code chooses not to investigate the application of the “zone of protection”, they have the option to ground and bond as they would if they were outside the “zone.”
Article 820 - Community Antenna Television and Radio Distribution Systems - Coaxial Cable

Informational Note: See Informational Note Figure 800(a) and Informational Note Figure 800(b) for an illustrative application of a bonding conductor or grounding electrode conductor.

Part I. General

820.1 Scope.

This article covers coaxial cable distribution of radio frequency signals typically employed in community antenna television (CATV) systems.

Informational Note: See 90.2(B)(4) for installations of CATV and radio distribution systems that are not covered.

820.2 Definitions.

See Part I of Article 100. For the purposes of this article, the following additional definitions apply.

Abandoned Coaxial Cable.

Installed coaxial cable that is not terminated at equipment other than a coaxial connector and not identified for future use with a tag.

Exposed (to Accidental Contact).

A circuit in such a position that, in case of failure of supports and or insulation, contact with another circuit may result.

Informational Note: See Part I of Article 100 for two other definitions of Exposed.

Point of Entrance.

The point within a building at which the coaxial cable emerges from an external wall, from a concrete floor slab, from rigid metal conduit (RMC), or from intermediate metal conduit (IMC).

Premises.

The land and buildings of a user located on the user side of utility-user network point of demarcation.

820.3 Other Articles.

Circuits and equipment shall comply with 820.3(A) through 820.3(I).

(A) Hazardous (Classified) Locations.

CATV equipment installed in a location that is classified in accordance with 500.5 and 505.5 shall comply with the applicable requirements of Chapter 5.

(B) Wiring in Ducts for Dust, Loose Stock, or Vapor Removal.

The requirements of 300.22(A) shall apply.

(C) Equipment in Other Space Used for Environmental Air.

The requirements of 300.22(C)(3) shall apply.

(D) Installation and Use.

The requirements of 110.3(B) shall apply.

(E) Installations of Conductive and Nonconductive Optical Fiber Cables.

The requirements of Article 770 shall apply.

(F) Communications Circuits.

The requirements of Article 800 shall apply.

(G) Network-Powered Broadband Communications Systems.

The requirements of Article 830 shall apply.

(H) Premises-Powered Broadband Communications Systems.

The requirements of Article 840 shall apply.

(I) Alternate Wiring Methods.

The wiring methods of Article 830 shall be permitted to substitute for the wiring methods of Article 820.

Informational Note: Use of Article 830 wiring methods will facilitate the upgrading of Article 820 installations to network-powered broadband applications.
820.15 Power Limitations.
Coaxial cable shall be permitted to deliver power to equipment that is directly associated with the radio frequency distribution system if the voltage is not over 60 volts and if the current is supplied by a transformer or other device that has power-limiting characteristics.

Power shall be blocked from premises devices on the network that are not intended to be powered via the coaxial cable.

820.21 Access to Electrical Equipment Behind Panels Designed to Allow Access.
Access to electrical equipment shall not be denied by an accumulation of coaxial cables that prevents removal of panels, including suspended ceiling panels.

820.24 Mechanical Execution of Work.
Community television and radio distribution systems shall be installed in a neat and workmanlike manner. Coaxial cables installed exposed on the surface of ceiling and sidewalls shall be supported by the building structure in such a manner that the cables will not be damaged by normal building use. Such cables shall be secured by hardware including straps, staples, cable ties, hangers, or similar fittings designed and installed so as not to damage the cable. The installation shall also conform to 300.4(D) and 300.11. Nonmetallic cable ties and other nonmetallic cable accessories used to secure and support cables in other spaces used for environmental air (plenums) shall be listed as having low smoke and heat release properties in accordance with 800.170(C).

Informational Note No. 2: See 4.3.11.2.6.5 and 4.3.11.5.5.6 of NFPA 90A-2015, Standard for the Installation of Air-Conditioning and Ventilating Systems, for discrete combustible components installed in accordance with 300.22(C).

Informational Note No. 3: Paint, plaster, cleaners, abrasives, corrosive residues, or other contaminants may result in an undetermined alteration of coaxial cable properties.

820.25 Abandoned Cables.
The accessible portion of abandoned coaxial cables shall be removed. Where cables are identified for future use with a tag, the tag shall be of sufficient durability to withstand the environment involved.

820.26 Spread of Fire or Products of Combustion.
Installations of coaxial cables and communications raceways in hollow spaces, vertical shafts, and ventilation or air-handling ducts shall be made so that the possible spread of fire or products of combustion will not be substantially increased. Openings around penetrations of coaxial cables and communications raceways through fire-resistant-rated walls, partitions, floors, or ceilings shall be firestopped using approved methods to maintain the fire resistance rating.

Informational Note: Directories of electrical construction materials published by qualified testing laboratories contain many listing installation restrictions necessary to maintain the fire-resistive rating of assemblies where penetrations or openings are made. Building codes also contain restrictions on membrane penetrations on opposite sides of a fire resistance–rated wall assembly. An example is the 600-mm (24-in.) minimum horizontal separation that usually applies between boxes installed on opposite sides of the wall. Assistance in complying with 820.26 can be found in building codes, fire resistance directories, and product listings.

Part II. Coaxial Cables Outside and Entering Buildings

820.44 Overhead (Aerial) Coaxial Cables.
Overhead (aerial) coaxial cables, prior to the point of grounding, as specified in 820.93, shall comply with 820.44(A) through 820.44(E).

(A) On Poles and In-Span.
Where coaxial cables and electric light or power conductors are supported by the same pole or are run parallel to each other in-span, the conditions described in 820.44(A)(1) through 820.44(A)(4) shall be met.

(1) Relative Location.
Where practicable, the coaxial cables shall be located below the electric light or power conductors.

(2) Attachment to Cross-Arms.
Coaxial cables shall not be attached to cross-arm that carries electric light or power conductors.

(3) Climbing Space.
The climbing space through coaxial cables shall comply with the requirements of 225.14(D).
Clearance.

Lead-in or overhead (aerial) - drop coaxial cables from a pole or other support, including the point of initial attachment to a building or structure, shall be kept away from electric light, power, Class 1, or non–power-limited fire alarm circuit conductors so as to avoid the possibility of accidental contact.

*Exception: Where proximity to electric light, power, Class 1, or non–power-limited fire alarm circuit conductors cannot be avoided, the installation shall provide clearances of not less than 300 mm (12 in.) from electric light, power, Class 1, or non–power-limited fire alarm circuit conductors. The clearance requirement shall apply at all points along the drop, and it shall increase to 1.0 m (40 in.) at the pole.*

Above Roofs.

Coaxial cables shall have a vertical clearance of not less than 2.5 m (8 ft) from all points of roofs above which they pass.

*Exception No. 1: Vertical clearance requirements shall not apply to auxiliary buildings such as garages and the like.*

*Exception No. 2: A reduction in clearance above only the overhanging portion of the roof to not less than 450 mm (18 in.) shall be permitted if (1) not more than 1.2 m (4 ft) of communications service drop conductors pass above the roof overhang, and (2) they are terminated at a raceway mast or other approved support.*

*Exception No. 3: Where the roof has a slope of not less than 100 mm in 300 mm (4 in. in 12 in.), a reduction in clearance to not less than 900 mm (3 ft) shall be permitted.*

On Masts.

Overhead (aerial) coaxial cables shall be permitted to be attached to an above-the-roof raceway mast that does not enclose or support conductors of electric light or power circuits.

Between Buildings.

Coaxial cables extending between buildings or structures, and also the supports or attachment fixtures, shall be identified and shall have sufficient strength to withstand the loads to which they might be subjected.

*Exception: Where a coaxial cable does not have sufficient strength to be self-supporting, it shall be attached to a supporting messenger cable that, together with the attachment fixtures or supports, shall be acceptable for the purpose and shall have sufficient strength to withstand the loads to which they may be subjected.*

On Buildings.

Where attached to buildings, coaxial cables shall be securely fastened in such a manner that they will be separated from other conductors in accordance with 820.44(E)(1), 820.44(E)(2), and 820.44(E)(3).

(1) Electric Light or Power.

The coaxial cable shall have a separation of at least 100 mm (4 in.) from electric light, power, Class 1, or non–power-limited fire alarm circuit conductors not in raceway or cable, or shall be permanently separated from conductors of the other system by a continuous and firmly fixed nonconductor in addition to the insulation on the wires.

(2) Other Communications Systems.

Coaxial cable shall be installed so that there will be no unnecessary interference in the maintenance of the separate systems. In no case shall the conductors, cables, messenger strand, or equipment of one system cause abrasion to the conductors, cable, messenger strand, or equipment of any other system.

(3) Lightning Conductors.

Where practicable, a separation of at least 1.8 m (6 ft) shall be maintained between any coaxial cable and lightning conductors.

*Informational Note No. 1: For additional information regarding overhead (aerial) wires and cables, see ANSI C2-2012, National Electrical Safety Code, Part 2, Safety Rules for Overhead Lines.*

*Informational Note No. 2: See Section 4.6 of NFPA 780-2014, Standard for the Installation of Lightning Protection Systems, for the calculation of sideflash distance.*

820.47 Underground Coaxial Cables Entering Buildings.

Underground coaxial cables entering buildings shall comply with 820.47(A) and 820.47(B).

(A) Underground Systems with Electric Light, Power, Class 1, or Non–Power-Limited Fire Alarm Circuit Conductors.

Underground coaxial cables in a duct, pedestal, handhole enclosure, or manhole that contains electric light, power, or Class 1 or non–power-limited fire alarm circuit conductors shall be in a section permanently separated from such conductors by means of a suitable barrier.

(B) Direct-Buried Cables and Raceways.

Direct-buried coaxial cable shall be separated at least 300 mm (12 in.) from conductors of any light or power, non–power-limited fire alarm circuit conductors, or Class 1 circuit.

*Exception No. 1: Separation shall not be required where electric service conductors or coaxial cables are installed in raceways or have metal cable armor.*

*Exception No. 2: Separation shall not be required where electric light or power branch-circuit or feeder conductors or Class 1 circuit conductors are installed in a raceway or in metal-sheathed, metal-clad, or Type UF or Type USE cables; or the coaxial cables have metal cable armor or are installed in a raceway.*
820.48 Unlisted Cables Entering Buildings.
Unlisted outside plant coaxial cables shall be permitted to be installed in building spaces other than risers, ducts used for environmental air, plenums used for environmental air, and other spaces used for environmental air, where the length of the cable within the building, measured from its point of entrance, does not exceed 15 m (50 ft) and the cable enters the building from the outside and is terminated at a grounding block. The point of entrance shall be permitted to be extended from the penetration of the external wall or floor slab to the point of emergence from the rigid metal conduit (RMC) or intermediate metal conduit (IMC) by continuously enclosing the entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC).

820.49 Metallic Entrance Conduit Grounding.
Metallic conduit containing entrance coaxial cable shall be connected by a bonding conductor or grounding electrode conductor to a grounding electrode in accordance with 820.100(B).

Part III. Protection

820.93 Grounding of the Outer Conductive Shield of Coaxial Cables.
Coaxial cables entering buildings or attached to buildings shall comply with 820.93(A) or (B). Where the outer conductive shield of a coaxial cable is grounded, no other protective devices shall be required. For purposes of this section, grounding located at mobile home service equipment located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, or at a mobile home disconnecting means grounded in accordance with 250.32 and located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, shall be considered to meet the requirements of this section.

Informational Note: Selecting a grounding block location to achieve the shortest practicable bonding conductor or grounding electrode conductor helps limit potential differences between CATV and other metallic systems.

(A) Entering Buildings.
In installations where the coaxial cable enters the building, the outer conductive shield shall be grounded in accordance with 820.100. The grounding shall be as close as practicable to the point of entrance.

(B) Terminating Outside of the Building.
In installations where the coaxial cable is terminated outside of the building, the outer conductive shield shall be grounded in accordance with 820.100. The grounding shall be as close as practicable to the point of attachment or termination.

(C) Location.
Where installed, a listed primary protector shall be applied on each community antenna and radio distribution (CATV) cable external to the premises. The listed primary protector shall be located as close as practicable to the entrance point of the cable on either side or integral to the ground block.

(D) Hazardous (Classified) Locations.
Where a primary protector or equipment providing the primary protection function is used, it shall not be located in any hazardous (classified) location as defined in 500.5 and 505.5 or in the vicinity of easily ignitible material.

Exception: As permitted in 501.150, 502.150, and 503.150.

Part IV. Grounding Methods

820.100 Cable Bonding and Grounding.
The shield of the coaxial cable shall be bonded or grounded as specified in 820.100(A) through (E).

Exception: For communications systems using coaxial cable completely contained within the building (i.e., they do not exit the building) or the exterior zone of protection defined by a 46 m (150 ft) radius rolling sphere and isolated from outside cable plant, the shield shall be permitted to be grounded by a connection to an equipment grounding conductor as described in 250.118. Connecting to an equipment grounding conductor through a grounded receptacle using a dedicated bonding jumper and a permanently connected listed device shall be permitted. Use of a cord and plug for the connection to an equipment grounding conductor shall not be permitted.

Informational Note: See 4.8.3.1 of NFPA 780-2014, Standard for the Installation of Lightning Protection Systems, for the theory of the term “rolling sphere.”

(A) Bonding Conductor or Grounding Electrode Conductor.

(1) Insulation.
The bonding conductor or grounding electrode conductor shall be listed and shall be permitted to be insulated, covered, or bare.

(2) Material.
The bonding conductor or grounding electrode conductor shall be copper or other corrosion-resistant conductive material, stranded or solid.

(3) Size.
The bonding conductor or grounding electrode conductor shall not be smaller than 14 AWG. It shall have a current-carrying capacity not less than the outer sheath of the coaxial cable. The bonding conductor or grounding electrode conductor shall not be required to exceed 6 AWG.
(4) Length.
The bonding conductor or grounding electrode conductor shall be as short as practicable. In one- and two-family dwellings, the bonding conductor or grounding electrode conductor shall be as short as practicable, not to exceed 6.0 m (20 ft) in length.

Informational Note: Similar bonding conductor or grounding electrode conductor length limitations applied at apartment buildings and commercial buildings help to reduce voltages that may be developed between the building's power and communications systems during lightning events.

Exception: In one- and two-family dwellings where it is not practicable to achieve an overall maximum bonding conductor or grounding electrode conductor length of 6.0 m (20 ft), a separate grounding electrode as specified in 250.52(A)(6), (A)(6), or (A)(7) shall be used, the grounding electrode conductor shall be connected to the separate grounding electrode in accordance with 250.70, and the separate grounding electrode shall be connected to the power grounding electrode system in accordance with 820.100(D).

(5) Run in Straight Line.
The bonding conductor or grounding electrode conductor shall be run in as straight a line as practicable.

(6) Physical Protection.
Bonding conductors and grounding electrode conductors shall be protected where exposed to physical damage. Where the bonding conductor or grounding electrode conductor is installed in a metal raceway, both ends of the raceway shall be bonded to the contained conductor or to the same terminal or electrode to which the bonding conductor or grounding electrode conductor is connected.

(B) Electrode.
The bonding conductor or grounding electrode conductor shall be connected in accordance with 820.100(B)(1), 820.100(B)(2), or 820.100(B)(3).

(1) In Buildings or Structures with an Intersystem Bonding Termination.
If the building or structure served has an intersystem bonding termination as required by 250.94, the bonding conductor shall be connected to the intersystem bonding termination.

(2) In Buildings or Structures with Grounding Means.
If the building or structure served has no intersystem bonding termination, the bonding conductor or grounding electrode conductor shall be connected to the nearest accessible location on one of the following:

   (1) The building or structure grounding electrode system as covered in 250.50
   (2) The grounded interior metal water piping system, within 1.5 m (5 ft) from its point of entrance to the building, as covered in 250.52
   (3) The power service accessible means external to enclosures using the options identified in the Exception of 250.94. If an intersystem bonding termination is established, all the rules of 250.94 shall apply.
   (4) The nonflexible metallic power service raceway
   (5) The service equipment enclosure
   (6) The grounding electrode conductor or the grounding electrode conductor metal enclosure of the power service, or
   (7) The grounding electrode conductor or the grounding electrode of a building or structure disconnecting means that is connected to an electrode as covered in 250.32

A bonding device intended to provide a termination point for the bonding conductor (intersystem bonding) shall not interfere with the opening of an equipment enclosure. A bonding device shall be mounted on nonremovable parts. A bonding device shall not be mounted on a door or cover even if the door or cover is nonremovable.

For purposes of this section, the mobile home service equipment or the mobile home disconnecting means, as described in 820.93, shall be considered accessible.

(3) In Buildings or Structures Without an Intersystem Bonding Termination or Grounding Means.
If the building or structure served has no intersystem bonding termination or grounding means, as described in 820.100(B)(2), the grounding electrode conductor shall be connected to the nearest one of the following:

   (1) To any one of the individual grounding electrodes described in 250.52(A)(1), (A)(2), (A)(3), or (A)(4).
   (2) If the building or structure served has no intersystem bonding termination or grounding means, as described in 820.100(B)(2) or (B)(3)(1), to any one of the individual grounding electrodes described in 250.52(A)(5), (A)(7), and (A)(8). Steam, hot water pipes, or lightning protection system conductors shall not be employed as grounding electrodes for bonding conductors or grounding electrode conductors.

(C) Electrode Connection.
Connections to grounding electrodes shall comply with 250.70.
Bonding of Electrodes.

A bonding jumper not smaller than 6 AWG copper or equivalent shall be connected between the community antenna television system's grounding electrode and the power grounding electrode system at the building or structure served where separate electrodes are used.

Exception: At mobile homes as covered in 820.106.

Informational Note No. 1: See 250.60 for connection to a lightning protection system.

Informational Note No. 2: Bonding together of all separate electrodes limits potential differences between them and between their associated wiring systems.

Shield Protection Devices.

Grounding of a coaxial drop cable shield by means of a protective device that does not interrupt the grounding system within the premises shall be permitted.

820.103 Equipment Grounding.

Unpowered equipment and enclosures or equipment powered by the coaxial cable shall be considered grounded where connected to the metallic cable shield.

820.106 Grounding and Bonding at Mobile Homes.

(A) Grounding.

Grounding shall comply with 820.106(A)(1) and (A)(2).

(1) Where there is no mobile home service equipment located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, the coaxial cable shield ground, or surge arrester grounding terminal, shall be connected to a grounding electrode conductor or grounding electrode in accordance with 820.100(B)(3).

(2) Where there is no mobile home disconnecting means grounded in accordance with 250.32 and located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, the coaxial cable shield ground, or surge arrester grounding terminal, shall be connected to a grounding electrode in accordance with 820.100(B)(3).

(B) Bonding.

The coaxial cable shield grounding terminal, surge arrester grounding terminal, or grounding electrode shall be connected to the metal frame or available grounding terminal of the mobile home with a copper conductor not smaller than 12 AWG under any of the following conditions:

(1) Where there is no mobile home service equipment or disconnecting means as in 820.106(A)

(2) Where the mobile home is supplied by cord and plug

Part V. Installation Methods Within Buildings

820.110 Raceways and Cable Routing Assemblies for Coaxial Cables.

(A) Types of Raceways.

Coaxial cables shall be permitted to be installed in any raceway that complies with either (A)(1) or (A)(2) and in cable routing assemblies installed in compliance with 820.110(C).

(1) Raceways Recognized in Chapter 3.

Coaxial cables shall be permitted to be installed in any raceway included in Chapter 3. The raceways shall be installed in accordance with the requirements of Chapter 3.

(2) Communications Raceways.

Coaxial cables shall be permitted to be installed in plenum communications raceways, riser communications raceways, and general-purpose communications raceways, selected in accordance with Table 800.154(b), listed in accordance with 800.182, and installed in accordance with 800.113 and 362.24 through 362.56, where the requirements applicable to electrical nonmetallic tubing (ENT) apply.

(3) Innerduct for Coaxial Cables.

Listed plenum communications raceways, listed riser communications raceways, and listed general-purpose communications raceways selected in accordance with the provisions of Table 800.154(b) shall be permitted to be installed as innerduct in any type of listed raceway permitted in Chapter 3.

(B) Raceway Fill for Coaxial Cables.

The raceway fill requirements of Chapters 3 and 9 shall not apply to coaxial cables.

(C) Cable Routing Assemblies.

Coaxial cables shall be permitted to be installed in plenum cable routing assemblies, riser cable routing assemblies, and general-purpose cable routing assemblies selected in accordance with Table 800.154(c), listed in accordance with 800.182, and installed in accordance with 800.110(C) and 800.113.

820.113 Installation of Coaxial Cables.

Installation of coaxial cables shall comply with 820.113(A) through (K). Installation of raceways and cable routing assemblies shall comply with 820.110.
Coaxial cables installed in buildings shall be listed.  
Exception: Coaxial cables that are installed in compliance with 820.48 shall not be required to be listed.

Ducts Specifically Fabricated for Environmental Air.
The following cables shall be permitted in ducts specifically fabricated for environmental air as described in 300.22(B) if they are directly associated with the air distribution system:

1. Up to 1.22 m (4 ft) of Type CATVP
2. Types CATVP, CATVR, CATV, and CATVX installed in raceways that are installed in compliance with 300.22(B)

Informational Note: For information on fire protection of wiring installed in fabricated ducts see 4.3.4.1 and 4.3.11.3.3 of NFPA 90A-2015, Standard for the Installation of Air-Conditioning and Ventilating Systems.

Other Spaces Used For Environmental Air (Plenums).
The following cables shall be permitted in other spaces used for environmental air as described in 300.22(C):

1. Type CATVP
2. Type CATVP installed in plenum communications raceways
3. Type CATVP installed in plenum cable routing assemblies
4. Type CATVP supported by open metallic cable trays or cable tray systems
5. Types CATVP, CATVR, CATV, and CATVX installed in raceways that are installed in compliance with 300.22(C)
6. Types CATVP, CATVR, CATV, and CATVX supported by solid-bottom metal cable trays with solid metal covers in other spaces used for environmental air (plenums) as described in 300.22(C)
7. Types CATVP, CATVR, CATV, and CATVX installed in plenum communications raceways, riser communications raceways, or general-purpose communications raceways supported by solid-bottom metal cable trays with solid metal covers in other spaces used for environmental air (plenums) as described in 300.22(C)

Informational Note: For information on fire protection of wiring installed in other spaces used for environmental air, see 4.3.11.2, 4.3.11.4, and 4.3.11.5 of NFPA 90A-2015, Standard for the Installation of Air-Conditioning and Ventilating Systems.

Risers — Cables in Vertical Runs.
The following cables shall be permitted in vertical runs penetrating one or more floors and in vertical runs in a shaft:

1. Types CATVP and CATVR
2. Types CATVP and CATVR installed in the following:
   3. Plenum communications raceways
   4. Plenum cable routing assemblies
   5. Riser communications raceways
   6. Riser cable routing assemblies

Informational Note: See 820.26 for firestop requirements for floor penetrations.

Risers — Cables and Innerducts in Metal Raceways.
The following cables and innerducts shall be permitted in metal raceways in a riser having firestops at each floor:

1. Types CATVP, CATVR, CATV, and CATVX
2. Types CATVP, CATVR, CATV, and CATVX installed in the following:
   3. Plenum communications raceways (innerduct)
   4. Riser communications raceways (innerduct)
   5. General-purpose communications raceways (innerduct)

Informational Note: See 820.26 for firestop requirements for floor penetrations.
(F) Risers — Cables in Fireproof Shafts.

The following cables shall be permitted to be installed in fireproof riser shafts with firestops at each floor:

1. Types CATVP, CATVR, CATV, and CATVX
2. Types CATVP, CATVR, and CATV installed in the following:
   3. Plenum communications raceways
   4. Plenum cable routing assemblies
   5. Riser communications raceways
   6. Riser cable routing assemblies
   7. General-purpose communications raceways
   8. General-purpose cable routing assemblies

Informational Note: See 820.26 for firestop requirements for floor penetrations.

(G) Risers — One- and Two-Family Dwellings.

The following cables shall be permitted in one- and two-family dwellings:

1. Types CATVP, CATVR, and CATV
2. Type CATVX less than 10 mm (\(\frac{3}{8}\) in.) in diameter
3. Types CATVP, CATVR, and CATV installed in the following:
   4. Plenum communications raceways
   5. Plenum cable routing assemblies
   6. Riser communications raceways
   7. Riser cable routing assemblies
   8. General-purpose communications raceways
   9. General-purpose cable routing assemblies

Informational Note: See 820.26 for firestop requirements for floor penetrations.

(H) Cable Trays.

The following cables shall be permitted to be supported by cable trays:

1. Types CATVP, CATVR, and CATV
2. Types CATVP, CATVR, and CATV installed in the following:
   3. Plenum communications raceways
   4. Riser communications raceways
   5. General-purpose communications raceways

(I) Distributing Frames and Cross-Connect Arrays.

The following cables shall be permitted to be installed in distributing frames and cross-connect arrays:

1. Types CATVP, CATVR, and CATV
2. Types CATVP, CATVR, and CATV installed in the following:
   3. Plenum communications raceways
   4. Plenum cable routing assemblies
   5. Riser communications raceways
   6. Riser cable routing assemblies
   7. General-purpose communications raceways
   8. General-purpose cable routing assemblies
Other Building Locations.

The following cables shall be permitted to be installed in building locations other than the locations covered in 820.113(B) through (I):

1. Types CATVP, CATVR, and CATV
2. A maximum of 3 m (10 ft) of exposed Type CATVX in nonconcealed spaces
3. Types CATVP, CATVR, and CATV installed in the following:
   4. Plenum communications raceways
   5. Plenum cable routing assemblies
   6. Riser communications raceways
   7. Riser cable routing assemblies
   8. General-purpose communications raceways
   9. General-purpose cable routing assemblies
10. Types CATVP, CATVR, CATV, and CATVX installed in a raceway of a type recognized in Chapter 3

One- and Two-Family and Multifamily Dwellings.

The following cables shall be permitted to be installed in one- and two-family and multifamily dwellings in locations other than those locations covered in 820.113(B) through (I):

1. Types CATVP, CATVR, and CATV
2. Type CATVX less than 10 mm (⅜ in.) in diameter
3. Types CATVP, CATVR, and CATV installed in the following:
   4. Plenum communications raceways
   5. Plenum cable routing assemblies
   6. Riser communications raceways
   7. Riser cable routing assemblies
   8. General-purpose communications raceways
   9. General-purpose cable routing assemblies
10. Types CATVP, CATVR, CATV, and CATVX installed in a raceway of a type recognized in Chapter 3

820.133 Installation of Coaxial Cables and Equipment.

Beyond the point of grounding, as defined in 820.93, the coaxial cable installation shall comply with 820.133(A) and (B).

(A) Separation from Other Conductors.
In Raceways, Cable Trays, Boxes, Enclosures, and Cable Routing Assemblies.

(a) Other Circuits. Coaxial cables shall be permitted in the same raceway, cable tray, box, enclosure, or cable routing assembly with jacketed cables of any of the following:

(2) Class 2 and Class 3 remote control, signaling, and power-limited circuits in compliance with Article 645 or Parts I and III of Article 725.

(3) Power-limited fire alarm systems in compliance with Parts I and III of Article 760.

(4) Nonconductive and conductive optical fiber cables in compliance with Parts I and V of Article 770.

(5) Communications circuits in compliance with Parts I and V of Article 800.

(6) Low-power network-powered broadband communications circuits in compliance with Parts I and V of Article 830.

(g) Electric Light, Power, Class 1, Non–Power-Limited Fire Alarm, and Medium-Power Network-Powered Broadband Communications Circuits. Coaxial cable shall not be placed in any raceway, compartment, outlet box, junction box, or other enclosures with conductors of electric light, power, Class 1, non–power-limited fire alarm, or medium-power network-powered broadband communications circuits.

Exception No. 1: Coaxial cable shall be permitted to be placed in any raceway, compartment, outlet box, junction box, or other enclosures with conductors of electric light, power, Class 1, non–power-limited fire alarm, or medium-power network-powered broadband communications circuits where all of the conductors of electric light, power, Class 1, non–power-limited fire alarm, and medium-power network-powered broadband communications circuits are separated from all of the coaxial cables by a permanent barrier or listed divider.

Exception No. 2: Coaxial cable shall be permitted to be placed in outlet boxes, junction boxes, or similar fittings or compartments with power conductors where such conductors are introduced solely for power supply to the coaxial cable system distribution equipment. The power circuit conductors shall be routed within the enclosure to maintain a minimum 6 mm (1/4 in.) separation from coaxial cables.

(2) Other Applications.

Coaxial cable shall be separated at least 50 mm (2 in.) from conductors of any electric light, power, Class 1, non–power-limited fire alarm, or medium-power network-powered broadband communications circuits.

Exception No. 1: Separation shall not be required where either (1) all of the conductors of electric light, power, Class 1, non–power-limited fire alarm, and medium-power network-powered broadband communications circuits are in a raceway, or in metal-sheathed, metal-clad, nonmetallic-sheathed, Type AC or Type UF cables, or (2) all of the coaxial cables are encased in a raceway.

Exception No. 2: Separation shall not be required where the coaxial cables are permanently separated from the conductors of electric light, power, Class 1, non–power-limited fire alarm, and medium-power network-powered broadband communications circuits by a continuous and firmly fixed nonconductor, such as porcelain tubes or flexible tubing, in addition to the insulation on the wire.

(B) Support of Coaxial Cables.

Raceways shall be used for their intended purpose. Coaxial cables shall not be strapped, taped, or attached by any means to the exterior of any conduit or raceway as a means of support.

Exception: Overhead (aerial) spans of coaxial cables shall be permitted to be attached to the exterior of a raceway-type mast intended for the attachment and support of such cables.
820.154 Applications of Listed CATV Cables.
Permitted and nonpermitted applications of listed coaxial cables shall be as indicated in Table 820.154(a). The permitted applications shall be subject to the installation requirements of 820.110 and 820.113. The substitutions for coaxial cables in Table 820.154(b) and illustrated in Figure 820.154 shall be permitted.

Informational Note: The substitute cables in Table 820.154(b) and Figure 820.154 are only coaxial-type cables.

Figure 820.154 Cable Substitution Hierarchy.

### Part VI. Listing Requirements

#### 820.179 Coaxial Cables.

Cables shall be listed in accordance with 820.179(A) through (D) and marked in accordance with Table 820.179. The cable voltage rating shall not be marked on the cable. Coaxial cables shall have a temperature rating of not less than 60°C (140°F). The temperature rating shall be marked on the jacket of coaxial cables that have a temperature rating exceeding 60°C (140°F).

Informational Note: Voltage markings on cables could be misinterpreted to suggest that the cables may be suitable for Class 1, electric light, and power applications.

**Exception:** Voltage markings shall be permitted where the cable has multiple listings and voltage marking is required for one or more of the listings.

(A) Type CATVP.

Type CATVP community antenna television plenum coaxial cables shall be listed as being suitable for use in ducts, plenums, and other spaces used for environmental air and shall also be listed as having adequate fire-resistant and low smoke-producing characteristics.

Informational Note: One method of defining a cable that is low smoke-producing cable and fire-resistant cable is that the cable exhibits a maximum peak optical density of 0.50 or less, an average optical density of 0.15 or less, and a maximum flame spread distance of 1.52 m (5 ft) or less when tested in accordance with NFPA 262-2015, *Standard Method of Test for Flame Travel and Smoke of Wires and Cables for Use in Air-Handling Spaces.*

(B) Type CATVR.

Type CATVR community antenna television riser coaxial cables shall be listed as being suitable for use in a vertical run in a shaft or from floor to floor and shall also be listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor.

Informational Note: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2011, *Standard Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts.*
(C) Type CATV.

Type CATV community antenna television coaxial cables shall be listed as being suitable for general-purpose CATV use, with the exception of risers and plenums, and shall also be listed as being resistant to the spread of fire.

Informational Note: One method of defining resistant to the spread of fire is that the cables do not spread fire to the top of the tray in the "UL Flame Exposure, Vertical Tray Flame Test" in ANSI/UL 1685-2010, Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables. The smoke measurements in the test method are not applicable.

Another method of defining resistant to the spread of fire is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA “Vertical Flame Test — Cables in Cable Trays,” as described in CSA C22.2 No. 0.3-09, Test Methods for Electrical Wires and Cables.

(D) Type CATVX.

Type CATVX limited-use community antenna television coaxial cables shall be listed as being suitable for use in dwellings and for use in raceways and shall also be listed as being resistant to flame spread.

Informational Note: One method of determining that cable is resistant to flame spread is by testing the cable to the VW-1 (vertical-wire) flame test in ANSI/UL 1581-2011, Reference Standard for Electrical Wires, Cables and Flexible Cords.

Informational Note: Cable types are listed in descending order of fire resistance rating.

820.180 Grounding Devices.

Where bonding or grounding is required, devices used to connect a shield, a sheath, or non–current-carrying metallic members of a cable to a bonding conductor, or grounding electrode conductor, shall be listed or be part of listed equipment.

Statement of Problem and Substantiation for Public Comment

Public input 1293 should have been accepted. When is coaxial cable installed that is not subject to the rules of Article 820? According to the panel, 820 doesn't regulate CCTV installations. Furthermore, the scope of 820 [820.1] clearly states the article covers coaxial cable, with CATV being an example of a location where one could find coaxial cable. "This article covers coaxial cable distribution...typically employed in CATV systems." Reading through 820, the only time you see the letters "CATV" is when those letters are describing coaxial cables. In other rules in the Code, for example 810.3, CATV isn't mentioned, but coaxial cable is.

Submittal Date: Fri Sep 25 16:10:54 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The panel rejects the title change. Article 820 is focused upon the application of coaxial cable with community antenna television and radio distribution systems, typically referred to as “cable TV” or “CATV”. There are other applications of coaxial cable such as communications and broadband systems. Revising the title of Article 820 to state only “Coaxial Cables” would broaden the scope of Article 820 into areas not covered by Article 820, but other Articles within the NEC.
Exposed (to Accidental Contact).
A circuit in such a position that, in case of failure of supports and or insulation, contact with another circuit may result.

Informational Note: See Part I of Article 100 for two other definitions of Exposed.

Statement of Problem and Substantiation for Public Comment

The Panel acted on PI 4519 and created FR 4512 that passed ballot. These two items deleted the Informational Note following 820.2, "Exposed (to Accidental Contact)". This is not indicated in the First Draft Report. We do NOT agree with the Panel action to delete the Informational Note. The term “Exposed” has multiple meanings throughout the NEC: uncovered and capable of being touched by persons, susceptible to physical damage, e.g., wiring attached to a surface, susceptible to power influences such as contact or induction, and susceptible to lightning influences, either a direct ‘hit’, induction or ground potential rise. Hence, the Informational Note provides clarity and should be maintained.

Committee Action: Rejected but see related SR
Resolution: SR-4556-NFPA 70-2015
Statement: The term “Exposed” has multiple meanings throughout the NEC: uncovered and capable of being touched by persons, susceptible to physical damage, e.g., wiring attached to a surface, susceptible to power influences such as contact or induction, and susceptible to lightning influences, either a direct ‘hit’, induction or ground potential rise. Hence, the informational note provides clarity and should be maintained.
Public Comment No. 458-NFPA 70-2015 [ Definition: Point of Entrance. ]

Point of Entrance.
The point within a building at which the coaxial cable emerges from an external wall or from a concrete floor slab, from rigid metal conduit (RMC), or from intermediate metal conduit (IMC).

Statement of Problem and Substantiation for Public Comment

Panel action on FR 4556 for 820.48 added “The point of entrance shall be permitted to be extended from the penetration of the external wall or floor slab to the point of emergence from the rigid metal conduit (RMC) or intermediate metal conduit (IMC) by continuously enclosing the entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC).”

This action is confusing unless the definition of point of entrance is modified to remove the text about the point of entrance being the point where the cable emerges from the RMC or the IMC.

This PC is offered as an alternative to PC 459. Similar PC are made for Article 770 sections and Article 800 sections.

Committee Statement

Committee Action: Accepted
Resolution: SR-4541-NFPA 70-2015
Statement: The definition “Point of Entrance” is simplified and potential confusion is avoided by locating the information regarding the application of rigid metal conduit (RMC) and intermediate metal conduit (IMC) in Section 820.48.
820.24 Mechanical Execution of Work.

Community television and radio distribution systems shall be installed in a neat and workmanlike manner. Coaxial cables installed exposed on the surface of ceiling and sidewalls shall be supported by the building structure in such a manner that the cables will not be damaged by normal building use. Such cables shall be secured by hardware including straps, staples, cable ties, hangers, or similar fittings designed and installed so as not to damage the cable. The installation shall also conform to 300.4(D) and 300.11. Nonmetallic cable ties and other nonmetallic cable accessories used to secure and support cables in other spaces used for environmental air (plenums) shall be listed as having low smoke and heat release properties in accordance with 800.170(C).

Informational Note No. 2: See 4.3.11.2.6.5 and 4.3.11.5.5.6 of NFPA 90A-2015, Standard for the Installation of Air-Conditioning and Ventilating Systems, for discrete combustible components installed in accordance with 300.22(C).

Informational Note No. 3: Paint, plaster, cleaners, abrasives, corrosive residues, or other contaminants may result in an undetermined alteration of coaxial cable properties.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4503-NFPA 70-2015
Statement: Telecommunications Industry Association (TIA) in its revision process corrected an error in their numbering scheme. Hence the two new parts are ANSI/TIA-568.0-D (generic) and ANSI/TIA-568.1-D (commercial buildings). Current editions of the documents are also provided. Additional TIA standards are added for completeness. The ANSI designation for TIA standards is retained as these standards utilize the ANSI standards development process and should be so designated.
Public Comment No. 202-NFPA 70-2015 [Section No. 820.48]

820.48 Unlisted Cables Entering Buildings.
Unlisted outside plant coaxial cables shall be permitted to be installed in building spaces other than risers, ducts used for environmental air, plenums used for environmental air, and other spaces used for environmental air, where the length of the cable within the building, measured from its point of entrance, does not exceed 15 m (50 ft) and the cable enters the building from the outside and is terminated at a grounding block.

Informational Note: The point of entrance may be permitted to be extended from the penetration of the external wall or floor slab to the point of emergence from the rigid metal conduit (RMC) or intermediate metal conduit (IMC) by continuously enclosing the entrance cables further into the building by continuing to enclose the entrance cable in rigid metal conduit (RMC) or intermediate metal conduit (IMC).

Statement of Problem and Substantiation for Public Comment

The proposed added text "The point of entrance shall be permitted to be extended from the penetration of the external wall or floor slab to the point of emergence from the rigid metal conduit (RMC) or intermediate metal conduit (IMC) by continuously enclosing the entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC)." is a cumbersome, run-on sentence that is both confusing and redundant. The definition, "point of entrance", currently and adequately defines RMC and IMC as acceptable vehicles establishing the point of entrance. If the Panel feels it is necessary to further clarify the use of RMC and IMC, greater clarity is provided by a simple Informational Note.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4542-NFPA 70-2015
Statement: The proposed added text clarifies the application of rigid metal conduit (RMC) and intermediate metal conduit (IMC) with unlisted cables entering buildings and eliminates potential confusion by permitting simplification of the definition "Point of Entrance" in 820.2. Inclusion as mandatory text instead of in the informational note permits and facilitates enforcement by the authority having jurisdiction (AHJ).
Public Comment No. 459-NFPA 70-2015 [Section No. 820.48]

820.48 Unlisted Cables Entering Buildings.

Unlisted outside plant coaxial cables shall be permitted to be installed in building spaces other than risers, ducts used for environmental air, plenums used for environmental air, and other spaces used for environmental air, where the length of the cable within the building, measured from its point of entrance, does not exceed 15 m (50 ft) and the cable enters the building from the outside and is terminated at a grounding block. The information note: Continuously enclosing entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC) extends the point of entrance shall be permitted to be extended from the penetration of the external wall or floor slab to the point of emergence from the rigid metal conduit (RMC) or intermediate metal conduit (IMC) by continuously enclosing the entrance cables in rigid metal conduit (RMC) or intermediate metal conduit (IMC).

Statement of Problem and Substantiation for Public Comment

The added text about extending the point of entrance was recommended to be an informational note in PI 1567. If the panel had adopted that recommendation, it would have avoided the confusion of permitting the extension of the point of entrance by using RMC or IMC when the point of entrance is already defined as the point emergence from RMC or IMC.

This PC is offered as an alternative to PC 458. Similar PC are made for Article 770 sections and Article 800 sections.

Inclusion as mandatory text instead of in the informational note permits and facilitates enforcement by the authority having jurisdiction (AHJ).
Section 820.49 is specific to metallic entrance conduit grounding. The only types of metallic entrance conduit permitted are RMC and IMC. Hence, in this section we are dealing only with RMC and IMC. While it is true that all metallic conduit should be grounded, such a general statement here may mislead the reader to incorrectly conclude that other types of metallic conduit may be used as entrance conduit.

Related Item
First Revision No. 4557-NFPA 70-2015 [Section No. 820.49]

Committee Statement
Committee Action: Rejected
Resolution: Other types of metal conduit besides RMC and IMC are permitted to be used as entrance conduit. All metal conduit is required to be bonded and grounded.
Public Comment No. 1877-NFPA 70-2015 [Section No. 820.100(B)(2)]

(2) In Buildings or Structures with Grounding Means.

If the building or structure served has no intersystem bonding termination, the bonding conductor or grounding electrode conductor shall be connected to the nearest accessible location on one of the following:

(1) The building or structure grounding electrode system as covered in 250.50

(2) The grounded interior metal water piping system, within 1.5 m (5 ft) from its point of entrance to the building, as covered in 250.52

(3) The power service accessible means external to enclosures using the options identified in the Exception of 250.94. If an intersystem bonding termination is established, all the rules of 250.94 shall apply.

(4) The nonflexible metallic power service raceway

(5) The service equipment enclosure

(6) The grounding electrode conductor or the grounding electrode conductor metal enclosure of the power service, or

(7) The grounding electrode conductor or the grounding electrode of a building or structure disconnecting means that is connected to an electrode as covered in 250.32

A bonding device intended to provide a termination point for the bonding conductor (intersystem bonding) shall not interfere with the opening of an equipment enclosure. A bonding device shall be mounted on nonremovable parts. A bonding device shall not be mounted on a door or cover even if the door or cover is nonremovable.

For purposes of this section, the mobile home service equipment or the mobile home disconnecting means, as described in 820.93, shall be considered accessible.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs the panel to review the list items for consistent language. List item 3 is inconsistent with the others.

Statement: The words "the provisions of" are superfluous and have been deleted.
Public Comment No. 205-NFPA 70-2015 [Section No. 820.113(C)]

(C) Other Spaces Used For Environmental Air (Plenums).
The following cables shall be permitted in other spaces used for environmental air as described in 300.22(C):

1. Type CATVP
2. Type CATVP installed in plenum communications raceways
3. Type CATVP installed in plenum cable routing assemblies
4. Type CATVP supported by open metallic cable trays or cable tray systems
5. Types CATVP, CATVR, CATV, and CATVX installed in raceways that are installed in compliance with 300.22(C)
6. Types CATVP, CATVR, CATV, and CATVX supported by solid-bottom metal cable trays with solid metal covers in other spaces used for environmental air (plenums) as described in 300.22(C)
7. Types CATVP, CATVR, CATV, and CATVX installed in plenum communications raceways, riser communications raceways, or general-purpose communications raceways supported by solid-bottom metal cable trays with solid metal covers in other spaces used for environmental air (plenums) as described in 300.22(C)

Informational Note: For information on fire protection of wiring installed in other spaces used for environmental air, see 4.3.11.2, 4.3.11.4, and 4.3.11.5 of NFPA 90A-2015, Standard for the Installation of Air-Conditioning and Ventilating Systems.

Statement of Problem and Substantiation for Public Comment

The second sentence of the Committee Statement to FR 4569, “The revised text clarifies that the only types of communications raceways and cable routing assemblies permitted must be listed as required in 800.182.” is not supported by the First Draft Report changes.

Submittal Date: Thu Jul 09 15:49:56 EDT 2015

Committee Statement
Committee Action: Rejected
Resolution: The Panel has identified a typographical error in the Committee Statement to FR 4569 in that the text “The revised text clarifies that the only types of communications raceways and cable routing assemblies permitted must be listed as required in 800.182.” does not apply to the First Draft revisions to 820.113(C).
820.179  Coaxial Cables.

Cables shall be listed in accordance with 820.179(A) through (D) and marked in accordance with Table 820.179. The cable voltage rating shall not be marked on the cable. Coaxial cables shall have a temperature rating of not less than 60°C (140°F). The temperature rating shall be marked on the jacket of coaxial cables that have a temperature rating exceeding 60°C (140°F).

Informational Note: Voltage markings on cables could be misinterpreted to suggest that the cables may be suitable for Class 1, electric light, and power applications.

Exception: Voltage markings shall be permitted where the cable has multiple listings and voltage marking is required for one or more of the listings.

(A) Type CATVP.

Type CATVP community antenna television plenum coaxial cables shall be listed as being suitable for use in ducts, plenums, and other spaces used for environmental air and shall also be listed as having adequate fire-resistant and low smoke-producing characteristics.

Informational Note: One method of defining a cable that is low smoke-producing cable and fire-resistant cable is that the cable exhibits a maximum peak optical density of 0.50 or less, an average optical density of 0.15 or less, and a maximum flame spread distance of 1.52 m (5 ft) or less when tested in accordance with NFPA 262-2015, Standard Method of Test for Flame Travel and Smoke of Wires and Cables for Use in Air-Handling Spaces.

(B) Type CATVR.

Type CATVR community antenna television riser coaxial cables shall be listed as being suitable for use in a vertical run in a shaft or from floor to floor and shall also be listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor.

Informational Note: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2011, Standard Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts.

(C) Type CATV.

Type CATV community antenna television coaxial cables shall be listed as being suitable for general-purpose CATV use, with the exception of risers and plenums, and shall also be listed as being resistant to the spread of fire.

Informational Note: One method of defining resistant to the spread of fire is that the cables do not spread fire to the top of the tray in the "UL Flame Exposure, Vertical Tray Flame Test" in ANSI/UL 1685-2010, Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables. The smoke measurements in the test method are not applicable.

Another method of defining resistant to the spread of fire is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA "Vertical Flame Test — Cables in Cable Trays," as described in CSA C22.2 No. 0.3-09, Test Methods for Electrical Wires and Cables.

(D) Type CATVX.

Type CATVX limited-use community antenna television coaxial cables shall be listed as being suitable for use in dwellings and for use in raceways and shall also be listed as being resistant to flame spread.

Informational Note: One method of determining that cable is resistant to flame spread is by testing the cable to the VW-1 (vertical-wire) flame test in ANSI/UL 1581-2011, Reference Standard for Electrical Wires, Cables and Flexible Cords.

Related Item

First Revision No. 4581-NFPA 70-2015 [Section No. 820.179]
Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4572-NFPA 70-2015 Due to some superfluous underlining of section and sub-section identifying numbers and letters, as well as in Table 820.179 in the PC, the PC could not be accepted as proposed.
Statement: Documents referenced in informational notes to 820.179(B) and (D) have been updated to the current edition.
Type CATVR community antenna television riser coaxial cables shall be listed as being suitable for use in a vertical run in a shaft or from floor to floor and shall also be listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor. Optionally, Type CATVR riser cables shall be permitted to be marked as Type CATVR ST1 if they are listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor and also listed as exhibiting limited smoke characteristics.

Informational Note 1: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2011, Standard Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts.

Informational Note 2: One method of defining optional limited smoke characteristics for riser cables is that the cables exhibit a peak smoke release rate not exceeding 0.40 m²/s and a total smoke released not exceeding 150 m² when tested in accordance with the requirements of CSA "Vertical Flame Test - Cables in Cable Trays," as described in CSA C22.2 No. 0.3-M-2009, Test Methods for Wires and Cables.

Statement of Problem and Substantiation for Public Comment

Please reconsider the action on this public input and accept the public comment. Smoke obscuration is a key fire safety problem. The reason that this additional optional listing and informational note are important is that there is no information in any of the test methods for fire propagation of cables how to test for smoke in riser cables. Such information is neither included in UL 1666 nor in CSA FT4 nor in UL 1685. Therefore there can be no standardized way for a manufacturer to demonstrate that a specific type of riser cables has lower smoke than typical riser cables. This is very different from the case of general purpose (or cable tray) cables. Both UL 1685 and CSA FT4 contain information on how to obtain "limited smoke" (meaning reduced smoke) cables that are general purpose cables. Therefore I understand the panel's objections to include optional markings for these cables. However, unless the code provides a systematic and standard way to determine what is a "limited smoke riser cable" the optional markings will not be able to be generated adequately.

A key aspect of wire and cable fire performance is smoke emission since it is well known that lack of visibility and smoke are serious problems in fire. In the NEC there is a designation for "low smoke cables", which are plenum-rated cables. There is also an optional designation of limited smoke cables, which is not required but applies to cable tray cables (tested to UL 1685 or CSA FT4). Riser cables are cables that usually are found in concealed spaces and it would be important to offer an optional marking for limited smoke riser cables, to distinguish them from standard riser cables. This is particularly useful for riser cables because, typically, riser cables are made with insulation and jacket materials that are very similar to CSA FT4 cables and also with materials that do not quite exhibit the flame and smoke characteristics of plenum cables. Therefore, manufacturers of materials who try to achieve a plenum cable rating, and can't quite make it, will often make their material slightly less safe from the point of view of smoke emission, in order to be able to save costs. This new optional marking would permit manufacturers to provide cables with both limited smoke and the flame spread characteristics of riser cable. The choice of criterion for the limited smoke riser cables (and the choice of designation) is based on the ST1 designation associated with the CSA FT4 test, when smoke emission is assessed.

This public comment is being proposed for all instances of riser cables and not public comment is proposed for optional markings of general purpose cables.

Submittal Date: Mon Sep 21 15:50:13 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: Optional marking is permitted. In reference to the informational note, it is inappropriate to include references to products that do not have a need for specific application rules or products that are permitted but not required by the NEC.
830.1 Scope.
This article covers network-powered broadband communications systems that provide any combination of voice, audio, video, data, and interactive services through a network interface unit.

Informational Note 1: A typical basic system configuration includes a cable supplying power and broadband signal to a network interface unit that converts the broadband signal to the component signals. Typical cables are coaxial cable with both broadband signal and power on the center conductor, composite metallic cable with a coaxial member(s) or twisted pair members for the broadband signal and twisted pair members for power, and composite optical fiber cable with a pair of conductors for power. Larger systems may also include network components such as amplifiers that require network power.

Informational Note 2: See 90.2(B)(4) for installations of broadband communications systems that are not covered.

Statement of Problem and Substantiation for Public Comment
Informational Note No. 2 referencing 90.2(B)(4) should not be deleted. It is extremely important, from a communications-provider point of view, that the reader and user of the Code be reminded that there are circumstances under which Article 830 does not apply. The presence of Informational Note No. 2 as contained in this Public Comment will help ensure that AHJs do not erroneously apply the requirements of Article 830 to facilities under the exclusive control of the communications utility.

Statement: Informational Note No. 2 referencing 90.2(B)(4) should not be deleted. It is extremely important, from a communications-provider point of view, that the reader and user of the Code be reminded that there are circumstances under which Article 830 does not apply.
Exposed (to Accidental Contact):
A circuit in such a position that, in case of failure of supports or insulation, contact with another circuit may result.

Informational Note: See Part 1 of Article 100 for two other definitions of Exposed.

Statement of Problem and Substantiation for Public Comment

The term “Exposed” has multiple meanings throughout the NEC: uncovered and capable of being touched by persons, susceptible to physical damage, e.g., wiring attached to a surface, susceptible to power influences such as contact or induction, and susceptible to lightning influences, either a direct ‘hit’, induction or ground potential rise. Hence, the Informational Note provides clarity and should be maintained.

Public Comment No. 195-NFPA 70-2015 [Section No. 830.24]

830.24 Mechanical Execution of Work.

Network-powered broadband communications circuits and equipment shall be installed in a neat and workmanlike manner. Cables installed exposed on the surface of ceilings and sidewalls shall be supported by the building structure in such a manner that the cable will not be damaged by normal building use. Such cables shall be secured by hardware including straps, staples, cable ties, hangers, or similar fittings designed and installed so as not to damage the cable. The installation shall also conform to 300.4(A), (D), (E), (F), and 300.11. Nonmetallic cable ties and other nonmetallic cable accessories used to secure and support cables in other spaces used for environmental air (plenums) shall be listed as having low smoke and heat release properties in accordance with 800.170(C).

Informational Note No. 2: See 4.3.11.2.6.5 and 4.3.11.5.5.6 of NFPA 90A-2015, Standard for the Installation of Air-Conditioning and Ventilating Systems, for discrete combustible components installed in accordance with 300.22(C).

Informational Note No. 3: Paint, plaster, cleaners, abrasives, corrosive residues, or other contaminants may result in an undetermined alteration of network-powered broadband cable properties.

Statement of Problem and Substantiation for Public Comment

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4503-NFPA 70-2015
Statement: Telecommunications Industry Association (TIA) in its revision process corrected an error in their numbering scheme. Hence the two new parts are ANSI/TIA-568.0-D (generic) and ANSI/TIA-568.1-D (commercial buildings). Current editions of the documents are also provided. Additional TIA standards are added for completeness. The ANSI designation for TIA standards is retained as these standards utilize the ANSI standards development process and should be so designated.
Public Comment No. 52-NFPA 70-2015 [ Section No. 830.44(C) ]

(C) Clearance from Ground.

Overhead (aerial) spans of network-powered broadband communications cables shall conform to not less than the following:

1. 2.9 m (9 1/2 ft) — above finished grade, sidewalks, or from any platform or projection from which they might be reached and accessible to pedestrians only

2. 3.5 m (11 1/2 ft) — over residential property and driveways, and those commercial areas not subject to truck traffic

3. 4.7 m (15 1/2 ft) — over public streets, alleys, roads, parking areas subject to truck traffic, driveways on other than residential property, and other land traversed by vehicles such as cultivated, grazing, forest, and orchard

Informational Note: These clearances have been specifically chosen to correlate with ANSI/IEEE C2-2012, National Electrical Safety Code, Table 232-1, which provides for clearances of wires, conductors, and cables above ground and roadways, rather than using the clearances referenced in 225.18. Because Article 800 and Article 820 have had no required clearances, the communications industry has used the clearances from the NESC for their installed cable plant.

Statement of Problem and Substantiation for Public Comment

Statement: C2-2012 was approved by ANSI on June 3, 2011 and is referenced to IEEE.

C2-2012 was approved by ANSI on June 3, 2011 and is referenced to IEEE.
(B) Direct-Buried Cables and Raceways.

Direct-buried network-powered broadband communications cables shall be separated by at least 300 mm (12 in.) from conductors of any light, power, non-power-limited fire alarm circuit conductors or Class 1 circuit.

Exception No. 1: Direct-buried network-powered broadband communications cables shall not be required to be separated by at least 300 mm (12 in.) from conductors of any light, power, non-power-limited fire alarm circuit conductors or Class 1 circuit. Separation shall not be required where electric service conductors or network-powered broadband communications cables are installed in raceways or have metal cable armor.

Exception No. 2: Direct-buried network-powered broadband communications cables. Separation shall not be required to be separated by at least 300 mm (12 in.) from conductors of any light, power, non-power-limited fire alarm circuit conductors or Class 1 circuit where electric light or power branch-circuit or feeder conductors, non-power-limited fire alarm circuit conductors, or Class 1 circuit conductors are installed in a raceway or in metal-sheathed, metal-clad, or Type UF or Type USE cables; or the network-powered broadband communications cables have metal cable armor or are installed in a raceway.

Statement of Problem and Substantiation for Public Comment

The text for both Exceptions 1 and 2 may be greatly simplified by stating: "Separation shall not be required where .....".

Statement: The text for both Exceptions 1 and 2 is simplified by stating: "Separation shall not be required where .....".
830.49 Metallic Entrance Conduit Grounding.

Metallic conduit, Rigid metal conduit (RMC) or intermediate metal conduit (IMC), containing network-powered broadband communications entrance cable shall be connected by a bonding conductor or grounding electrode conductor to a grounding electrode in accordance with 830.100(B).

Statement of Problem and Substantiation for Public Comment

Section 830.49 is specific to metallic entrance conduit grounding. The only types of metallic entrance conduit permitted are RMC and IMC. Hence, in this section we are dealing only with RMC and IMC. While it is true that all metallic conduit should be grounded, such a general statement here may mislead the reader to incorrectly conclude that other types of metallic conduit may be used as entrance conduit.

Submittal Date: Mon Jul 13 16:21:53 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: Other types of metal conduit besides RMC and IMC are permitted to be used as entrance conduit. All metal conduit is required to be bonded and grounded.
In Buildings or Structures with Grounding Means.

If the building or structure served has no intersystem bonding termination, the bonding conductor or grounding electrode conductor shall be connected to the nearest accessible location on one of the following:

1. The building or structure grounding electrode system as covered in 250.50
2. The grounded interior metal water piping system, within 1.5 m (5 ft) from its point of entrance to the building, as covered in 250.52
3. The power service accessible means external to enclosures using the options identified in the Exception of 250.94. If an intersystem bonding termination is established, all the rules of 250.94 shall apply.
4. The nonflexible metallic power service raceway
5. The service equipment enclosure
6. The grounding electrode conductor or the grounding electrode conductor metal enclosure of the power service
7. The grounding electrode conductor or the grounding electrode of a building or structure disconnecting means that is connected to an electrode as covered in 250.32

A bonding device intended to provide a termination point for the bonding conductor (intersystem bonding) shall not interfere with the opening of an equipment enclosure. A bonding device shall be mounted on nonremovable parts. A bonding device shall not be mounted on a door or cover even if the door or cover is nonremovable.

For purposes of this section, the mobile home service equipment or the mobile home disconnecting means, as described in 830.93, shall be considered accessible.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs the panel to review the list items for consistent language. List item 3 is inconsistent with the others. The Correlating Committee also directs the panel to review the language in 830.100(B)(2)(3) and revise “Exception of” to “Exception to.”

Resolution: The serial commas are editorially correct.
Public Comment No. 230-NFPA 70-2015 [Section No. 830.113(I)]

(I) Other Building Locations.

The following cables shall be permitted to be installed in building locations other than those covered in 830.113(B) through (G):

1. Types BLP, BMR, BLR, BM, and BL
2. Types BLP, BMR, BLR, BM, BL, and BLX installed in raceways recognized in Chapter 3.
3. Types BLP, BLR, and BL installed in the following:
   4. Plenum communications raceways
   5. Plenum cable routing assemblies
   6. Riser communications raceways
   7. Riser cable routing assemblies
   8. General-purpose communications raceways
   9. General-purpose cable routing assemblies
10. Type BLX less than 10 mm (3/8 in.) in diameter in one- and two-family dwellings
11. Types BMU and BLU entering the building from outside and run in rigid metal conduit (RMC) or intermediate metal conduit (IMC) where the conduit is connected by a bonding conductor or grounding electrode conductor in accordance with 830.100(B)

Informational Note: This provision limits the length of Type BLX cable to 15 m (50 ft), while 830.90(B) requires that the primary protector, or NIU with integral protection, be located as close as practicable to the point at which the cable enters the building. Therefore, in installations requiring a primary protector, or NIU with integral protection, Type BLX cable may not be permitted to extend 15 m (50 ft) into the building if it is practicable to place the primary protector closer than 15 m (50 ft) to the entrance point.

12. A maximum length of 15 m (50 ft), within the building, of Type BLX cable entering the building from outside and terminating at an NIU or a primary protection location

Statement of Problem and Substantiation for Public Comment

Item (I)(2) needs to clarify what type of raceways are permitted. The term “raceway” is too general and may include all types of raceway, e.g., communications raceway. Medium-power cables are not permitted in Communications raceway.

Resolution: SR-4553-NFPA 70-2015
Statement: The revised text clarifies what type of raceways are permitted. The term “raceway” is too general and may include all types of raceway, e.g., communications raceway. The reference to 830.113(B) through (G) is corrected to 830.113(B) through (H) because a new section 830.113(H) was inserted in the first draft stage.
(2) Other Applications.

Network-powered broadband communications cable shall be separated at least 50 mm (2 in.) from conductors of any electric light, power, Class 1, and non–power-limited fire alarm circuits.

Exception No. 1: Network-powered broadband communications cable Separation shall not be required to be separated at least 50 mm (2 in.) from conductors of any electric light, power, Class 1, and non–power-limited fire alarm circuits where—
either (1) all of the conductors of electric light, power, Class 1, and non–power-limited fire alarm circuits are in a raceway, or in metal-sheathed, metal-clad, nonmetallic-sheathed, Type AC, or Type UF cables, or (2) all of the network-powered broadband communications cables are encased in a raceway.

Exception No. 2: Network-powered broadband communications cable Separation shall not be required to be separated at least 50 mm (2 in.) from conductors of any electric light, power, Class 1, and non–power-limited fire alarm circuits where the network-powered broadband communications cables are permanently separated from the conductors of electric light, power, Class 1, and non–power-limited fire alarm circuits by a continuous and firmly fixed nonconductor, such as porcelain tubes or flexible tubing, in addition to the insulation on the wire.

Statement of Problem and Substantiation for Public Comment

The text of Exception Nos. 1 and 2 may be greatly simplified by stating “Separation shall not be required where…” rather than repeating the full text of the introductory paragraph.

Committee Action: Accepted
Resolution: SR-4570-NFPA 70-2015
Statement: The text of Exception Nos. 1 and 2 is simplified by stating “Separation shall not be required where…” rather than repeating the full text of the introductory paragraph.
830.154. Applications of Network-Powered Broadband Communications System Cables.
Permitted and nonpermitted applications of listed network-powered broadband communications system cables shall be as indicated in Table 830.154(a). The permitted applications shall be subject to the installation requirements of 830.40, 830.110, and 830.113. The substitutions for network-powered broadband system cables listed in Table 830.154(b) shall be permitted.

### Statement of Problem and Substantiation for Public Comment

The sentence "The definition of Point of Entrance is in 830.2." of Informational Note No. 1 to Table 830.154(a) is incorrectly struck out. It is only the third sentence that should be struck as indicated in the Committee Statement where it is stated: “It is sufficient that IN No. 1 direct the reader to the definition in 830.2 thus avoiding potential confusion.”

### Committee Statement

- **Committee Action:** Accepted
- **Resolution:** SR-4555-NFPA 70-2015
- **Statement:** The sentence "The definition of Point of Entrance is in 830.2." of Informational Note No. 1 to Table 830.154(a) is inadvertently struck out in the First Draft. It is only the third sentence that should be struck as indicated in the First Revision Committee Statement where it is stated: “It is sufficient that IN No. 1 direct the reader to the definition in 830.2 thus avoiding potential confusion.”
Type BMR cables shall be listed as being suitable for use in a vertical run in a shaft or from floor to floor and shall also be listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor. Optionally, Type BMR riser cables shall be permitted to be marked as Type BMR ST1 if they are listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor and also listed as exhibiting limited smoke characteristics.

Informational Note 1: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2011, Standard Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts.

Informational Note 2: One method of defining optional limited smoke characteristics for riser cables is that the cables exhibit a peak smoke release rate not exceeding 0.40 m²/s and a total smoke released not exceeding 150 m² when tested in accordance with the requirements of CSA, "Vertical Flame Test - Cables in Cable Trays," as described in CSA C22.2 No. 0.3-M-2009, Test Methods for Wires and Cables.

Statement of Problem and Substantiation for Public Comment

Please reconsider the action on this public input and accept the public comment. Smoke obscuration is a key fire safety problem.

The reason that this additional optional listing and informational note are important is that there is no information in any of the test methods for fire propagation of cables how to test for smoke in riser cables. Such information is neither included in UL 1666 nor in CSA FT4 nor in UL 1685. Therefore there can be no standardized way for a manufacturer to demonstrate that a specific type of riser cables has lower smoke than typical riser cables. This is very different from the case of general purpose (or cable tray) cables. Both UL 1685 and CSA FT4 contain information on how to obtain "limited smoke" (meaning reduced smoke) cables that are general purpose cables. Therefore I understand the panel's objections to include optional markings for these cables. However, unless the code provides a systematic and standard way to determine what is a "limited smoke riser cable" the optional markings will not be able to be generated adequately.

A key aspect of wire and cable fire performance is smoke emission since it is well known that lack of visibility and smoke are serious problems in fire. In the NEC there is a designation for "low smoke cables", which are plenum-rated cables. There is also an optional designation of limited smoke cables, which is not required but applies to cable tray cables (tested to UL 1685 or CSA FT4). Riser cables are cables that usually are found in concealed spaces and it would be important to offer an optional marking for limited smoke riser cables, to distinguish them from standard riser cables. This is particularly useful for riser cables because, typically, riser cables are made with insulation and jacket materials that are very similar to CSA FT4 cables and also with materials that do not quite exhibit the flame and smoke characteristics of plenum cables. Therefore, manufacturers of materials who try to achieve a plenum cable rating, and can't quite make it, will often make their material slightly less safe from the point of view of smoke emission, in order to be able to save costs. This new optional marking would permit manufacturers to provide cables with both limited smoke and the flame spread characteristics of riser cable. The choice of criterion for the limited smoke riser cables (and the choice of designation) is based on the ST1 designation associated with the CSA FT4 test, when smoke emission is assessed.

This public comment is being proposed for all instances of riser cables and not public comment is proposed for optional markings of general purpose cables.

Public Comment No. 233-NFPA 70-2015 [Section No. 840.3(E)]

(E) Output Circuits.
As appropriate for the services provided, the output circuits derived from the network terminal shall comply with the requirements of the following:

1. Installations of communications circuits — Part V of Article 800
2. Installations of premises (within buildings) community antenna television and radio distribution circuits — Part V of Article 820
3. Installations of optical fiber cables — Part V of Article 770
4. Installations of Class 2 and Class 3 circuits — Part III of Article 725

Informational Note: See 725.121 for information on the classification of information technology equipment circuits.

5. Installations of power-limited fire alarm circuits — Part III of Article 760

Statement of Problem and Substantiation for Public Comment

The word “premises” includes areas outside the building. If the Panel intends that the requirement of 840.3(E)(2) apply within buildings as stated in the Committee Statement, then it should specifically state “within buildings”. See Panel Action on FR 4559, 820.100, Exception.

Committee Statement

Committee Action: Accepted
Resolution: SR-4571-NFPA 70-2015
Statement: The word “premises” also includes areas outside the building. The requirement of 840.3(E)(2) applies only within buildings and this second revision specifically clarifies this.
(B) Above Roofs.
Outside plant optical fiber cables shall have a vertical clearance of not less than 2.5 m (8 ft) from all points of roofs above which they pass.

Exception No. 1: Vertical clearance requirements shall not apply to auxiliary buildings, such as garages and the like.

Exception No. 2: A reduction in clearance above only the overhanging portion of the roof, to not less than 450 mm (18 in.), shall be permitted if (a) not more than 1.2 m (4 ft) of premises-powered broadband communications service-drop cable passes above the roof overhang, and (b) the cable is terminated at a through- or above-the-roof raceway or approved support.

Exception No. 3: Where the roof has a slope of not less than 100 mm in 300 mm (4 in. in 12 in.), a reduction in clearance to not less than 900 mm (3 ft) shall be permitted.

Informational Note: For additional information regarding overhead wires and cables, see IEEE C2-2012, National Electrical Safety Code, Part 2, Safety Rules for Overhead Lines.

Statement of Problem and Substantiation for Public Comment
Corrected reference from ANSI to IEEE in information note for exception #3.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4558-NFPA 70-2015
Statement: C2-2012 was approved by ANSI on June 3, 2011 and is referenced to IEEE.
Underground wires and cables entering buildings shall comply with 840.47(A) through (C).

(A) Optical Fiber Cables.

(1) Class 1 or Non–Power-Limited Fire Alarm Circuits.
Underground conductive optical fiber cables with a non–current-carrying metallic member entering buildings with electric light, power, Class 1, or non–power-limited fire alarm circuit conductors in a raceway, handhole enclosure, or manhole shall be located in a section separated from such conductors by means of brick, concrete, or tile partitions or by means of a suitable barrier.

(2) Direct-Buried Cables.
Direct-buried conductive optical fiber cables with a non–current-carrying metallic member shall be separated by at least 300 mm (12 in.) from conductors of any electric light, power, or non–power-limited fire alarm circuit conductors or Class 1 circuit.

Exception No. 1: Direct-buried premises-powered broadband communications cables shall not be required to be separated by at least 300 mm (12 in.) from conductors of any light, power, non–power-limited fire alarm circuit conductors or Class 1 circuit where the electric service conductors are installed in raceways or have metal cable armor.

Exception No. 2: Direct-buried premises-powered broadband communications cables shall not be required to be separated by at least 300 mm (12 in.) from conductors of any light, power, non–power-limited fire alarm circuit conductors or Class 1 circuit where the electric light or power branch-circuit or feeder conductors, non–power-limited fire alarm circuit conductors, or Class 1 circuit conductors are installed in a raceway or in metal-sheathed, metal-clad, or Type UF or Type USE cables.

(3) Mechanical Protection.
Direct-buried cable, conduit, or other raceway shall be installed to have a minimum cover of 150 mm (6 in.).

(B) Communications Wires and Cables.
Installations of communications wires and multipair communications cables shall comply with 800.47.

(C) Coaxial Cables.
Installations of coaxial cables shall comply with 820.47.

Statement of Problem and Substantiation for Public Comment

The primary purpose of this Public comment is to correct errors. The opening sentence should require compliance with 840.47(A) through (C), not 840.47(A)(1) through (C).

Section 840.47(A)(2) deals with fiber optic cables, not premises powered broadband communications cables. The recommended text corrects that error. It also simplifies the text of the exceptions.

“Optical fiber cables with a non-current-carrying metallic member” are conductive optical fiber cables. The recommended text uses “conductive optical fiber cables” instead of “optical fiber cables with a non-current-carrying metallic member”. The definition of a conductive optical fiber cable is:

Conductive Optical Fiber Cable. A factory assembly of one or more optical fibers having an overall covering and containing non–current-carrying conductive member(s) such as metallic strength member(s), metallic vapor barrier(s), metallic armor or metallic sheath.

Section 840.47(A)(2) deals with optical fiber cables, not premises powered broadband communications cables. The revised text corrects that error and also simplifies the text of the exceptions. “Optical fiber cables with a non-current-carrying metallic member” are conductive optical fiber cables. The revised text uses “conductive optical fiber cables” instead of “optical fiber cables with a non-current-carrying metallic member.”
Public Comment No. 234-NFPA 70-2015 [ Section No. 840.47(A)(2) ]

(2) Direct-Buried Cables.

Direct-buried optical fiber cables with a non–current-carrying metallic member shall be separated by at least 300 mm (12 in.) from conductors of any electric light, power, or non–power-limited fire alarm circuit conductors or Class 1 circuit.

Exception No. 1: Direct-buried premises-powered broadband communications cables. Separation shall not be required to be separated by at least 300 mm (12 in.) from conductors of any light, power, non–power-limited fire alarm circuit conductors or Class 1 circuit where electric service conductors are installed in raceways or have metal cable armor.

Exception No. 2: Direct-buried premises-powered broadband communications cables. Separation shall not be required to be separated by at least 300 mm (12 in.) from conductors of any light, power, non–power-limited fire alarm circuit conductors or Class 1 circuit where electric light or power branch-circuit or feeder conductors, non–power-limited fire alarm circuit conductors, or Class 1 circuit conductors are installed in a raceway or in metal-sheathed, metal-clad, or Type UF or Type USE cables.

Statement of Problem and Substantiation for Public Comment

Exception Nos. 1 and 2 refer to “direct-buried premises-powered broadband communications cables” which is much too broad. This section deals only with optical fiber cables as identified in 800.47(A) and described in the introductory text to 840.47(A)(2) that states “Direct-buried optical fiber cables with non-current carrying metallic member ....”. Further, Exception Nos. 1 and 2 may be greatly simplified by stating “Separation shall not be required where....” rather than repeating the majority of the text of the introductory paragraph.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4559-NFPA 70-2015
Statement: The opening sentence should require compliance with 840.47(A) through (C), not 840.47(A)(1) through (C).

Section 840.47(A)(2) deals with optical fiber cables, not premises powered broadband communications cables. The revised text corrects that error and also simplifies the text of the exceptions. “Optical fiber cables with a non-current-carrying metallic member” are conductive optical fiber cables. The revised text uses “conductive optical fiber cables” instead of “optical fiber cables with a non-current-carrying metallic member”.
Public Comment No. 24-NFPA 70-2015 [Section No. 840.48]

### 840.48 Unlisted Wires and Cables Entering Buildings.
Installations of unlisted wires and cables entering buildings shall comply with 840.48(A), (B), or (C), as applicable.

(A) Optical Fiber Cables.
Installations of unlisted optical fiber cables entering buildings shall comply with 770.48.

(B) Communications Wires and Cables.
Installations of unlisted communications wires and unlisted multipair communications cables entering buildings shall comply with 800.48.

(C) Coaxial Cables.
Installations of unlisted coaxial cables entering buildings shall comply with 820.48.

### Statement of Problem and Substantiation for Public Comment
This is an editorial Public Comment. The title of 840.48 includes “wires”. The opening sentence should also include “wires”.

Submittal Date: Tue Jun 23 00:17:15 EDT 2015

### Committee Statement
Committee Action: Rejected
Resolution: Section 800.173 has listing requirements for communications drop wire. Section 800.48 only permits unlisted cables, not unlisted wires, to enter a building.
Installations of unlisted wires and cables entering buildings shall comply with 840.48(A), through (B D), or (C), as applicable.

Statement of Problem and Substantiation for Public Comment

The introductory text is revised to reflect the section title. The subsection list is expanded to accommodate the addition of a new subsection for communications wires. This is a companion comment to Public Comments 237 and 239.

Committee Statement

Committee Action: Rejected
Resolution: Section 800.173 has listing requirements for communications drop wire. Section 800.48 only permits unlisted cables, not unlisted wires, to enter a building.
(B) Communications Wires and Cables.
Installations of unlisted communications wires and unlisted multipair communications cables entering buildings shall comply with 800.48.

(C) Communications wires.
Installations of communications wires entering buildings shall comply with 800.48 as pertains to communications cables.

Statement of Problem and Substantiation for Public Comment

Section 800.48 does not address communications wires. Hence, stating in 840.48(B) that "Installations of unlisted communications wires and unlisted multipair communications cables entering buildings shall comply with 800.48" is misleading. A new subsection (C) is added to address communications wires. The word "multipair" is deleted as it is redundant. The term "cable" is defined in 800.2 as "A factory assembly of two or more conductors having an overall covering.", i.e., multicord. This is a companion comment to Public Comments 236 and 239.

**Public Comment No. 1032-NFPA 70-2015 [Section No. 840.160]**

**840.160 - Powering Circuits.**

Communications cables, in addition to carrying the communications circuit, shall also be permitted to carry circuits for powering communications equipment. The communications cables and the powering circuits shall comply with 840.160(A), (B), and (C), as applicable.

(A) - Power Limitations.

The power circuits shall comply with the requirements of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc.

Informational Note: The 100 VA (100 W) power source maximum nameplate rating in Chapter 9, Table 11(B) is the same as the maximum power rating for network-powered broadband communications systems in Table 830.15, the communications industry standard in ATIS-0600337.2010, Requirements for Maximum Voltage, Current, and Power Levels in Network-Powered Transport Systems, and UL 60950.1, Information Technology Equipment Safety Part 21: Remote Power Feeding.

**Table 840.160(A) Communications Conductor Ampacity Based on Copper Conductors at Ambient Temperature of 30°C (86°F), Conductor Temperature 60°C (140°F)**

<table>
<thead>
<tr>
<th>Conductor Size (AWG)</th>
<th>Ampacity of Each Conductor in a Single 4-Pair Multipair Communications Cable Installed Separated from All Other Cables</th>
<th>Ampacity of Each Conductor in a Multipair Communications Cable when More Than One Cable Is Installed Together or the Multipair Cable Is Larger Than 4 Pairs</th>
</tr>
</thead>

<td>1.1</td>
</tr>
<tr>
<td>22</td>
<td>3.1</td>
<td>1.5</td>
</tr>
</tbody>
</table>

Informational Note: The conductor size of existing communications cable, including "category X" type cables, can be as small as 26 AWG.

(B) - Ampacity.

The maximum current carried by each communications conductor shall conform to Table 840.160(A).

Informational Note: The ampacity of the small wire gauges used in communications cables are not included in the ampacity tables in Article 310.

(C) - Installations of New Cables.

New cables installed for carrying both communications and power, where the maximum adjusted ampacity of conductors exceed the values in Table 840.160(A), shall be Type CMP-LP, CMR-LP, or CM-LP, as applicable.

(D) - Using Cables Without the "LP" Marking for Supplying Premises Power and Communications.

New and existing cables without the "LP" marking shall be permitted to connect to communications equipment that supplies communications and power in accordance with the voltage and power limitations of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc, provided that the maximum current supplied by the power source is less than the adjusted ampacity of conductors in Table 840.160(A). For ambient temperatures other that 30°C (86°F) ampacity shall be permitted to be adjusted per Table 310.15(B)(2)(a).

**Statement of Problem and Substantiation for Public Comment**

- Combinations of cable types, AWGs, installation conditions, and usage conditions makes this a very complex task requiring further detailed investigations
- Working in isolation can lead to an incomplete, simplistic, and premature solutions that could negatively impact the industry and the market
- The industry has managed power delivery over communications cables for 10 years now with no documented record of loss
- This management and safeguards by the industry, individual manufacturers, and owners/operators will continue to evolve and improve in the future and should be taken into account
- Introduction of new LP class of cables is premature without the necessary review and refinement by the industry

As project leader of ISO/IEC/SC 25/WG 3 TR 29125 remote powering task group, we would like to work together with regulatory organizations like NEC and IEC TC 64 to develop appropriate requirements that will continue to keep remote powering a safe and popular application.

Informational Note: The conductor size of existing communications cables, including “category X” type cables, can be as small as 26 AWG.

(B) . Ampacity.
The maximum current carried by each communications conductor shall conform to Table 840.160(A).

Informational Note: The ampacity of the small wire gauges used in communications cables are not included in the ampacity tables in Article 310.

(C) . Installations of New Cables.
New cables installed for carrying both communications and power, where the maximum adjusted ampacity of conductors exceed the values in Table 840.160(A), shall be Type CMP-LP, CMR-LP, or CM-LP, as applicable.

(D) . Using Cables Without the “LP” Marking for Supplying Premises Power and Communications.
New and existing cables without the “LP” marking shall be permitted to connect to communications equipment that supplies communications and power in accordance with the voltage and power limitations of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc, provided that the maximum current supplied by the power source is less than the adjusted ampacity of conductors in Table 840.160(A). For ambient temperatures other than 30°C (86°F) ampacity shall be permitted to be adjusted per Table 310.15(B)(2)(a).

Statement of Problem and Substantiation for Public Comment

This section should be resolved due to inadequate technical substantiation. Chapter 3 of the NEC deals with power conductors. This section is more suitable as part of Article 725 which covers remote control, signaling, and power limited circuits that are not an integral part of a device or appliance. Equipment or devices connected to such cables also may be subject to voltages exceeding their original intended maximum values.

</tr>
</tbody>
</table>

Informational Note: The conductor size of existing communications cable, including “category X” type cables, can be as small as 26 AWG.

(B) Ampacity.

The maximum current carried by each communications conductor greater than 0.5A shall conform to Table 840.160(A).

Informational Note: The ampacity of the small wire gauges used in communications cables are not included in the ampacity tables in Article 310.

(C) Installations of New Cables.

New cables installed for carrying both communications and power, where the maximum adjusted ampacity of conductors exceed the values in Table 840.160(A), shall greater than 0.5A per conductor or greater than 100 watts per cable shall be Type CMP-LP, CRM-LP, or CM-LP, as applicable.

(D) Using Cables Without the “LP” Marking for Supplying Premises Power and Communications.

New and existing cables without carrying both communications and power less than or equal to 0.5A per conductor or less than or equal to 100 watts per cable without the “LP” marking shall be permitted to connect to communications equipment that supplies communications and power in accordance with the voltage and power limitations of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc provided that the maximum current supplied by the power source is less than the adjusted ampacity of conductors in Table 840.160(A). For ambient temperatures other than 30°C (86°F) ampacity shall be permitted to be adjusted per Table 310.15(B)(a).

(E) Cables and Equipment Marking Supplying Premises Power and Communications.

Data cables connected to a powering circuit sourcing greater than 0.5A per conductor or greater than 100 watts per cable must be identified with a red tape circling at minimum 3 times around the cable on each end within 6 inches from the connector. Powering circuits supplying more than 0.5A per conductor or greater than 100 watts per cable must be clearly labeled on the equipment face plate in maximum watts per port.

Statement of Problem and Substantiation for Public Comment

1) The table 840.160(A) has not been verified for accuracy or test methodology in accordance with TIA cabling guidance.
2) The new LP cable classification has not been demonstrated as applicable in any data cabling implementation. TIA and IEEE802.3 have done little to no work verifying the cable can carry data.
3) There are currently no power over data ports in telecommunications that support more than 100 watts per cable. It may be true that there exist power sources delivering only power at the higher wattage, but it is not true that telecom gear exists in such capacity.
4) Technology in the data port for ports carrying power over data greater than 100 watts does not exist and will not be developed by the telecommunications industry.
5) The RJ-45 connection system simply cannot carry adequately more than 1.0A per conductor on a good day.

Statement of Problem and Substantiation for Public Comment

Extensive testing done at UL LLC has shown that cable bundling greatly influences heat dissipation. Consequently, the table needs to be revised to account for bundle sizes as well as the temperature rating of the cables.

See the UL Fact Finding Report on Power over Local Area Network Type Cables (4-Pair Data / Communications Cables) for supporting data.

Committee Action: Rejected but see related SR
Resolution: SR-4564-NFPA 70-2015
Statement: The requirements proposed in the First Draft are outside the scope of Chapter 8 as well as the title and scope of Article 840. However, wording was added to direct the user to 725.144 for power delivery circuits that exceed 60 watts on communications cables.

Communications cables, in addition to carrying the communications circuit, shall also be permitted to carry circuits for powering communications equipment. The communications cables and the powering circuits shall comply with 840.160(A), (B), and (C), as applicable.

(A). Power Limitations.

The power circuits shall comply with the requirements of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc.

Informational Note: The 100 VA (100 W) power source maximum nameplate rating in Chapter 9, Table 11(B) is the same as the maximum power rating for network-powered broadband communications systems in Table 830.15, the communications industry standard in ATIS-0600337 2010, Requirements for Maximum Voltage, Current, and Power Levels in Network-Powered Transport Systems, and UL 60950-2, Information Technology Equipment Safety Part 21: Remote Power Feeding.

</tbody>
</table>

Informational Note: The conductor size of existing communications cable, including “category X” type cables, can be as small as 26 AWG.

(B). Ampacity.

The maximum current carried by each communications conductor shall conform to Table 840.160(A).

Informational Note: The ampacity of the small wire gauges used in communications cables are not included in the ampacity tables in Article 310.

(C). Installations of New Cables.

New cables installed for carrying both communications and power, where the maximum adjusted ampacity of conductors exceed the values in Table 840.160(A), shall be Type CMP-LP, CMR-LP, or CM-LP, as applicable.

(D). Using Cables Without the “LP” Marking for Supplying Premises Power and Communications.

New and existing cables without the “LP” marking shall be permitted to connect to communications equipment that supplies communications and power in accordance with the voltage and power limitations of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc, provided that the maximum current supplied by the power source is less than the adjusted ampacity of conductors in Table 840.160(A). For ambient temperatures other than 30°C (86°F) ampacity shall be permitted to be adjusted per Table 310.15(B)(2)(a).

Additional Proposed Changes

Statement of Problem and Substantiation for Public Comment

The addition of new section VI on premises powering of communications equipment over communications cables is premature and not based on a demonstrated record of loss. This results in several technical errors which are both unjustified and confusing to the reader. I respectfully request that the matter be held over to the 2020 code cycle to determine what, if any, restrictions are necessary, and provide adequate opportunity for peer review by industry-expert bodies.

I am an actively participating member of both the IEEE 802.3 working group (including the IEEE 802.3bt Power over MDI Task Force) and the TIA TR42.7 Copper Cabling Subcommittee. I have spent considerable time reviewing data relevant to the most widespread use of power over data cabling today – that based on IEEE Std. 802.3 Clause 33 Data Terminal Equipment Power via Media Dependent Interface (MDI). Systems designed to IEEE Std. 802.3 Clause 33 limits make up the overwhelming majority of “Power over Ethernet” systems, but, as discussed below, the term is abused. I am also familiar with specifications for power over HDBASE-T, as they currently exist. In years of investigation, in industry committees with collective experience of tens of millions of ports, I am not aware of any documented instances of fire hazard caused by overheating of wiring. Additionally, when questioned in these groups, advocates for the proposed changes have repeatedly failed to cite any such instances.

Perhaps as a consequence of both the lack of technical justification and adequate public review of data, there are several fatal flaws in the currently proposed section VI, which would benefit from postponing any inclusions until the 2020 code cycle. By that time, extensive
reviews in process in several industry standards bodies with cross-industry experts will be complete. Some of the flaws in the existing proposed section are listed below:

- The ‘informational note’ that begins the section offers NO SPECIFIC GUIDANCE as to what might be considered included in the clause. It only references ‘Including Power over Ethernet’, which is itself an imprecise and often abused term, but, if one wishes to equate it to only those systems in the IEEE Standard for Ethernet (802.3-2012), would result in amperage levels that are specifically below those mentioned in the section (hence this cannot be the meaning). The informational note only adds confusion, listing no specific applications included, excluding others, as well as suggesting some as included which are specifically below the power levels addressed.

- Proposed Section 840.160 (A) provides for voltage sources up to 60 V dc, and references Chapter 9, Table 11(B). This is not a requirement on the communications cabling, but rather on power sources. Application to this section is inappropriate for several technical reasons, including that Table 11(B) of Chapter 9 speaks to current limits which vary inversely with voltage, and hence, is inappropriate to relate to heating of cabling due to current.

- Proposed Table 840.160 (A) provides for current levels in single cable instances that are incompatible with the interfaces used in conjunction with the data ports on communications equipment today. Continuous currents of greater than 1A per conductor, suggested by the table, are outside the technology used today on communications ports providing power and are not provided today, to the best of my knowledge.

- Proposed Table 840.160 (A), mandated by 840.160(B) and (D) for existing cabling types, is inappropriately applied to the types of cabling used in premises broadband data communications equipment. The record of contributions and experience brought by members of the TIA TR42.7 Copper Cabling committee in the preparation of TIA TSB-184 and TIA-TSB-184-A (in progress) has clearly shown the wide variation of cable heating with relation to current in communications cabling. It particularly shows variation based on not only conductor diameter (which the proposed table captures), but also several uncaptured parameters, including cable construction, the number of cables bundled, the percentage of cables carrying current, and the environment (e.g., conduit or free air) that the cabling is in. Additionally, data gathered by UL, which has yet to be peer-reviewed and is in conflict with other well-reviewed data, has shown this same variability. The proposed table captures none of these effects, and erroneously suggests that even 2 cables provides a substantially worse heating environment than a single one, equivalent to bundles of hundreds. At this stage, efforts to substitute tables or add substantial additional content at this stage would suffer from lack of time for detailed public input. Experience shows that even with expert bodies, this is a subject that requires careful comparisons of measurements, methodology and results. Without an urgent technical justification, any material addition or substitution in the proposed code would suffer from inadequate review.

- Proposed Section 840.160 (C) mandates a currently unknown and uncharacterized class of cabling, ‘-LP’ cabling. It is unknown whether such cabling is available, whether it is appropriate for communications applications, and what the amperage of the proposed –LP cabling would be. To the best of my knowledge, there is currently no –LP listed cabling in use. The inclusion of this section requires trust in a specification that would be promulgated with minimal peer-review, without any practical experience, and still without any demonstrated record of loss that it is supposedly addressing.

Industry standards bodies have carefully addressed the conditions for supplying power along with data over premises cabling, and have consistently applied limitations that keep them under both SELV, and Class 2 LPS limits on a per-cable (generally 8 conductors) basis. They have considered and continue to consider the limits of cable heating. Open industry-standard forums provide a forum to evaluate concerns and give guidance to continue to avoid a record of loss. For these reasons, in view of the above, and lack of technical justification, deletion of these flawed sections now, and consideration for the 2020 code is the prudent course of action.

(C). Installations of New Cables.
New cables installed for carrying both communications and power, where the maximum adjusted ampacity of conductors exceed the values in Table 840.160(A), shall be Type CMP-LP, CMR-LP, or CM-LP, as applicable.

(D). Using Cables Without the “LP” Marking for Supplying Premises Power and Communications.
New and existing cables without the “LP” marking shall be permitted to connect to communications equipment that supplies communications and power in accordance with the voltage and power limitations of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc, provided that the maximum current supplied by the power source is less than the adjusted ampacity of conductors in Table 840.160(A). For ambient temperatures other than 30°C (86°F) ampacity shall be permitted to be adjusted per Table 310.15(B)(2)(a).

Deletion of the entire contents of FR4643, hold for further action in 2020 NEC revision cycle.

Statement of Problem and Substantiation for Public Comment

Individual members of the Ethernet Alliance have reviewed the proposed First Revision No. 4643-NFPA 70-2015 submitted by CMP 16 proposing the addition of a new Part VI to article 840 addressing remote powering over data communication cables. This comment is endorsed by the Ethernet Alliance. The Ethernet Alliance is a global consortium of system and component vendors, industry experts, and university and government professionals who are committed to the success and expansion of IEEE 802 Ethernet technologies. “Power over Ethernet” has become a generic term used in the marketplace for remote powering schemes. Some of these schemes abuse this term and may not even be compatible with IEEE Std 802.3 Clause 33 Data Terminal Equipment (DTE) Power via Media Dependent Interface (MDI) remote powering or data communication standards.

The Ethernet Alliance recognizes the general issue in the industry using the term “Power over Ethernet”, and its association with IEEE Std 802.3 Clause 33 DTE Power via MDI. For the past year, the Ethernet Alliance PoE Subcommittee members have been working to create a PoE Logo Certification program intended for the industry to identify actual remote powering systems designed in accordance with IEEE Std 802.3 Clause 33 DTE Power via MDI.

It is important to recognize that systems designed per IEEE Std 802.3 Clause 33 DTE Power via MDI specifications do not exceed the limitations of Safety Extra Low Voltage (SELV) and Limited Power Source (LPS) use a maximum of 100 VA per eight-conductor cable as a limiting condition for remote powering applications. Additionally, there has always been an IEEE Std 802.3 consideration as the cable’s data communication degrades as a function of increased temperature.

Notwithstanding the above, for the following reasons, the individual members of the Ethernet Alliance believe this change to the code is premature and should be deferred to the 2020 code revision cycle in order to allow all interested and affected parties sufficient time to review and comment:

• No Demonstrated Record of Loss

Based on market data from the Dell’Oro Group which provides market information about the telecommunications, networking, and data center IT industries, hundreds of millions of PoE Ethernet Switch Ports, Internet Protocol Desk Phones and Enterprise Wireless LAN...
Access Points utilizing IEEE Std 802.3 Clause 33 DTE Power via MDI compliant remote powering have shipped. To our best knowledge, there is no demonstrated record of loss attributed to the implementation of this standard. Furthermore, we are not aware of any safety related issues cited in general industry or US Consumer Product Safety Commission notices that would justify the proposed change.

- Insufficient Technical Justification
  We are not aware of any available data to support the proposed changes in FR4643 prior to the written submission deadline. Any data provided after this deadline would not permit sufficient time for industry review and comment.

- Lack of LP Cable Specification
  Prior to the written submission deadline, we are not aware of any available LP cable specifications, certification procedures or vendors manufacturing LP cables. Any information provided after this deadline would not permit sufficient time for industry review and comment.

Statement of Problem and Substantiation for Public Comment

Statement of Problem and Substantiation

I am submitting this comment on behalf of Dell Inc., which is a supplier of solutions that support IEEE Std 802.3 Clause 33 DTE Power via MDI, which is. This comment is to address the proposed First Revision No. 4643-NFPA70-2015 submitted by CMP 16 proposing the addition of a new Part VI to article 840 addressing remote powering over data communication cables.

Dell is concerned about the lack of any available data prior to the written submission deadline that supports the proposed changes in FR4643. We are also unaware of any available LP cable specifications, certification procedures or vendors manufacturing LP cables. Both types of data are necessary with adequate time to allow the industry to sufficiently review and comment.

Furthermore, as a supplier of equipment that supports IEEE Std 802.3 Clause 33 DTE Power via MDI compliant remote powering, to the best of our knowledge, we are unaware of any demonstrated records of loss. We are, also, not aware of any safety related issues cited in general industry or US Consumer Product Safety Commission notices that would justify the proposed change.

Given the stated concerns above, we believe this change to the code is premature and should be deferred to the 2020 code revision cycle in order to allow all interested and affected parties sufficient time to review and comment.

First Revision No. 4643-NFPA 70-2015 [Global Input]
Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4564-NFPA 70-2015
Statement: The requirements proposed in the First Draft are outside the scope of Chapter 8 as well as the title and scope of Article 840. However, wording was added to direct the user to 725.144 for power delivery circuits that exceed 60 watts on communications cables.
840.160 Powering Circuits.

Communications cables, in addition to carrying the communications circuit, shall also be permitted to carry circuits for powering communications equipment. The communications cables and the powering circuits shall greater than 0.5A per conductor or greater than 100 watts per cable in accordance with the voltage and power limitations of Table 11(B) in chapter 9 for sources up to 60V dc shall comply with 840.160(A), (B), and (C), (D) and (E), as applicable.

(A) Power Limitations.
The power circuits shall comply with the requirements of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc.

Informational Note: The 100 VA (100 W) power source maximum nameplate rating in Chapter 9, Table 11(B) is the same as the maximum power rating for network-powered broadband communications systems in Table 830.15, the communications industry standard in ATIS-0600337.2010, Requirements for Maximum Voltage, Current, and Power Levels in Network-Powered Transport Systems, and UL 60950-1, Information Technology Equipment Safety Part 21: Remote Power Feeding.

<tr>
<td>22</td>
<td>3.1</td>
<td>1.5</td>
</tr>
</tbody>
</table>

Informational Note: The conductor size of existing communications cable, including "category X" type cables, can be as small as 26 AWG.

(B) Ampacity.
The maximum current carried by each communications conductor, greater than 0.5A, shall conform to Table 840.160(A).

Informational Note: The ampacity of the small wire gauges used in communications cables are not included in the ampacity tables in Article 310.

(C) Installations of New Cables.
New cables installed for carrying both communications and power, where the maximum adjusted ampacity of conductors exceed the values in Table 840.160(A), shall greater than 0.5A per conductor or greater than 100 watts per cable shall be Type CMP-LP, CMR-LP, or CM-LP, as applicable.

(D) Using Cables Without the “LP” Marking for Supplying Premises Power and Communications.
New and existing cables without carrying both communications and power less than or equal to 0.5A per conductor or less than or equal to 100 watts per cable without the "LP" marking shall be permitted to connect to communications equipment that supplies communications and power in accordance with the voltage and power limitations of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc, provided that the maximum current supplied by the power source is less than the adjusted ampacity of conductors in Table to 60 V dc.

(E) Cables and Equipment Marking Supplying Premises Power and Communications.
Data cables connected to a powering circuit sourcing greater than 0.5A per conductor or greater than 100 watts per cable shall be identified with a red band comprising tape circling at minimum 3 times around the cable or equivalent permanent marking on each end within 6 inches from the connector. Powering circuits supplying more than 0.5A per conductor or greater than 100 watts per cable shall be clearly labeled on the equipment face plate in maximum watts per port.

Justification
1) The table 840.160(A)
   For ambient temperatures other than 30°C (86°F) ampacity shall be permitted to be adjusted per Table 310.15(B)(2)(a), has not been verified for accuracy or test methodology in accordance with TIA cabling guidance.
2) The new LP cable classification has not been demonstrated as applicable in any data cabling implementation. TIA and IEEE802.3 have not verified that this cable can carry data.
3) There are currently no power over data ports in telecommunications that support more than 100 watts per cable. Power sources capable of delivering only power at higher wattage do exist, but it is not true that telecom gear exists in such capacity.

4) Technology in the data port for ports carrying power over data greater than 100 watts does not currently exist and is not planned to be developed by the telecommunications industry.

5) The RJ-45 connection system in use for data communications cannot safely carry more than 1.0A per conductor, regardless of the associated cable wire gauge.

Statement of Problem and Substantiation for Public Comment

Clarification of the current and power limitations related to communications circuit wiring is needed. Provision is needed to address the lack of qualification of "LP" cables for data communications, hence provision must be made to address the use of non "LP" cables in existing and new installations. Data circuits (equipment and cables) sourcing or carrying high (> 0.5 A per conductor or >100 W per cable) should carry identification marking to distinguish from data only or low power cables. Lastly, the current carrying capacity of the RJ-45 connectors typically used for data communications circuits should be recognized.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4564-NFPA 70-2015
Statement: The requirements proposed in the First Draft are outside the scope of Chapter 8 as well as the title and scope of Article 840. However, wording was added to direct the user to 725.144 for power delivery circuits that exceed 60 watts on communications cables.
840.160, Powering Circuits.

Communications cables, in addition to carrying the communications circuit, shall also be permitted to carry circuits for powering communications equipment. The communications cables and the powering circuits shall comply with 840.160(A), (B), and (C) and (D), as applicable.

(A) Power Limitations.

The power circuits shall comply with the requirements of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc.

Informational Note: The 100 VA (100 W) power source maximum nameplate rating in Chapter 9, Table 11(B) is the same as the maximum power rating for network-powered broadband communications systems in Table 830.15, the communications industry standard in ATIS-0600337.2010, Requirements for Maximum Voltage, Current, and Power Levels in Network-Powered Transport Systems, and UL 6095021, Information Technology Equipment Safety Part 21: Requirements for Maximum Voltage, Current, and Power Levels in Network-Powered Transport Systems.

Table 840.160(A) Communications Conductor Ampacity Based on Copper Conductors at Ambient Temperature of 30°C (86°F), Conductor Temperature 60°C (140°F)

<table>

<td>3.1</td>
<td>1.5</td>
</tr>
</tbody>
</table>

Informational Note: The conductor size of existing communications cable, including “category X” type cables, can be as small as 26 AWG.

(B) Ampacity.

The maximum current carried by each communications conductor shall conform to Table 840.160(A).

Informational Note: The ampacity of the small wire gauges used in communications cables are not included in the ampacity tables in Article 310.

(C) Installations of New Cables.

New cables installed for carrying both communications and power, where the maximum listed Communication Cables, including listed Limited Power Communication Cables (CMP-LP, CMR-LP and CM-LP), installed shall be permitted to connect to equipment that supplies communications and power in accordance with the voltage and power limitations of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc, provided that the maximum current supplied by the power source is less than the adjusted ampacity of conductors in Table 840.160(A). For ambient temperatures other that 30°C (86°F) ampacity shall be permitted to be adjusted per Table 310.15(B)(2)(a).

(D) Using Existing Cables Without the “LP” Marking for Supplying Premises Power and Communications.

New and existing cables without the “LP” marking shall be permitted to connect to communications equipment that supplies communications and power in accordance with the voltage and power limitations of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc, provided that the maximum current supplied by the power source is less than the adjusted ampacity of conductors in Table 840.160(A). For ambient temperatures other that 30°C (86°F) ampacity shall be permitted to be adjusted per Table 310.15(B)(2)(a).

Statement of Problem and Substantiation for Public Comment

Communication Cables are connected to equipment other than Communication equipment for power delivery (e.g. Cameras, Monitor, Lights) and text modified to show this. Ampacity limits need to apply to both new and existing communication cables, regardless of optional markings, and text modified to show this. Text regarding optional marking “LP” cables changed as it has not been adequately defined or adequately shown that it can safely operate at higher current (Ampacity) than Communication Cables. It is unclear how LP listed cables will have different Ampacity than non LP listed communication cables with same wire gauge and temperature rating for...
worst-case ambient thermal conditions and worst-case heating produced by the maximum permissible current being carried by the cables. As it is an optional marking, they are not precluded as long as they meet all requirements of communication cable.

Public Comment No. 696-NFPA 70-2015 [ Section No. 840.160 ]

840.160 - Powering Circuits.
Communications cables, in addition to carrying the communications circuit, shall also be permitted to carry circuits for powering communications equipment. The communications cables and the powering circuits shall comply with 840.160(A), (B), and (C), as applicable.

(A) - Power Limitations.
The power circuits shall comply with the requirements of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc.

Informational Note: The 100 VA (100 W) power source maximum nameplate rating in Chapter 9, Table 11(B) is the same as the maximum power rating for network-powered broadband communications systems in Table 830.15, the communications industry standard in ATIS-0600337.2010, Requirements for Maximum Voltage, Current, and Power Levels in Network-Powered Transport Systems, and UL 60950-21, Information Technology Equipment Safety Part 21: Remote Power Feeding.

</tr>
</tbody>
</table>

Informational Note: The conductor size of existing communications cable, including “category X” type cables, can be as small as 26 AWG.

(B) - Ampacity.
The maximum current carried by each communications conductor shall conform to Table 840.160(A).

Informational Note: The ampacity of the small wire gauges used in communications cables are not included in the ampacity tables in Article 310.

(C) - Installations of New Cables.
New cables installed for carrying both communications and power, where the maximum adjusted ampacity of conductors exceed the values in Table 840.160(A), shall be Type CMP-LP, CMR-LP, or CM-LP, as applicable.

(D) - Using Cables Without the “LP” Marking for Supplying Premises Power and Communications.
New and existing cables without the “LP” marking shall be permitted to connect to communications equipment that supplies communications and power in accordance with the voltage and power limitations of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc, provided that the maximum current supplied by the power source is less than the adjusted ampacity of conductors in Table 840.160(A).
For ambient temperatures other than 30°C (86°F), ampacity shall be permitted to be adjusted per Table 310.15(B)(2)(a).

Statement of Problem and Substantiation for Public Comment

Electrical safety is extremely important and as such any action to reduce real risks is worthwhile to pursue. As such, we see that IEEE Power over DTE is a valuable technology due to the large number of safeguards that it mandates:
- Unless plugged in to a valid device, there is no voltage on the cable greater than a few volts, limited to very small power.
- During operation, both unplugging of the load, over-current and short-circuit are constantly monitored and action taken in case of an abnormal situation.
- PoE loads (PDs) are required to shut down in case the loop resistance of the cable exceeds the maximum supported.

We also note that there is a very large number of PoE ports operating in the field today. Across all these ports, we are not aware of a single instance of an unsafe situation arising due to the use of Power over Ethernet within the limits of IEEE 802.3.

The proposed addition to the NEC 4643-NFPA 70-2015 has been produced without consultation of the relevant group of PoE experts in the IEEE 802.3bt task group.

The comment also introduces a new form of cabling, for which no specification currently exists. This seems to preclude proper review of the proposed addition.

For this reason, and considering that there is no demonstrated incident of loss pressing safety problem to address, this addition to the NEC should be postponed to the next revision of the Code. In this way, both BICSI and the cabling experts can contribute to a quality solution to be proposed for the 2020 version of NEC.

Consequently IEEE 802.3 BICSI as well as many individual companies affected by these proposed changes, including Philips, will file a comment on the proposed draft. A comment by BICSI to the effect of postponing action to the 2020 Code cycle revision would seem appropriate.

BICSI is very interested in arranging collaboration between the NEC Panel 16, ISO/IEC/JTC 1/ SC 25/WG 3, TIA TR42 IEC TC 64, IEEE 802.3, HDBase-T, CCCA and BICSI Standards in this effort.

Informational Note: The conductor size of existing communications cable, including “category X” type cables, can be as
small as 26 AWG.

(B)  Ampacity.

The maximum current carried by each communications conductor shall conform to Table 840.160(A).

Informational Note: The ampacity of the small wire gauges used in communications cables are not included in the
ampacity tables in Article 310.

(C)  Installations of New Cables.

New cables installed for carrying both communications and power, where the maximum adjusted ampacity of conductors
exceed the values in Table 840.160(A), shall be Type CMP-LP, CMR-LP, or CM-LP, as applicable.

(D)  Using Cables Without the “LP” Marking for Supplying Premises Power and Communications.

New and existing cables without the “LP” marking shall be permitted to connect to communications equipment that supplies
communications and power in accordance with the voltage and power limitations of Table 11(B) in Chapter 9 for voltage
sources up to 60 V dc, provided that the maximum current supplied by the power source is less than the adjusted ampacity
of conductors in Table 840.160(A). For ambient temperatures other than 30°C (86°F) ampacity shall be permitted to be adjusted
per Table 310.15(B)(2)(a).

Statement of Problem and Substantiation for Public Comment

The work in this section was not performed with and/or coordinated with the international standards group responsible for Power-
Over-Ethernet specifications; specifically the IEEE 802.3 Ethernet Working Group. Until such a time as such coordination exists, do not
put forth any code language for power over twisted pair cabling.

Informational Note: The conductor size of existing communications cable, including "category X" type cables, can be as small as 26 AWG.

(B) Ampacity.

The maximum current carried by each communications conductor shall conform to Table 840.160(A).

Informational Note: The ampacity of the small wire gauges used in communications cables are not included in the ampacity tables in Article 310.

(C) Installations of New Cables.

New cables installed for carrying both communications and power, where the maximum adjusted ampacity of conductors exceed the values in Table 840.160(A), shall be Type CMP-LP, CMR-LP, or CM-LP, as applicable.

(D) Using Cables Without the "LP" Marking for Supplying Premises Power and Communications.

New and existing cables without the "LP" marking shall be permitted to connect to communications equipment that supplies communications and power in accordance with the voltage and power limitations of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc, provided that the maximum current supplied by the power source is less than the adjusted ampacity of conductors in Table 840.160(A). For ambient temperatures other that 30°C (86°F), ampacity shall be permitted to be adjusted per Table 310.15(B)(2)(a).

Statement of Problem and Substantiation for Public Comment

For the following reasons, we (Panduit) believe that this particular code change requires more investigative time to sufficiently evaluate the real nature of the issue and allow the technical community (especially the 802.3 working group of the IEEE and the TIA TR42.7 group whose membership represent industry experts from a broad spectrum of equipment providers and users of the equipment) to assist in the characterization of power on communication cable. We recommend that at a minimum that this code change be deferred to the 2020 or later code revision so that ample time for a thorough technical analysis can be completed.

Concerns with the present version of the proposed code change

1. The proposed code change as it is, will create confusion to the industry
   With the lack of clear and holistic specifications on the proposed LP cable, it will be very difficult for communication cable manufacturers as well as installers to understand how best to proceed.

2. Wire AWG, Cable construction and Material Selection control temperature rise above ambient
   An ampacity table as proposed where the controlling variable is only wire AWG is necessary but not sufficient in specifying maximum ampacity for a given rise above ambient. Although 28 AWG cable is widely used in the industry it is not included in the ampacity tables. The IEEE 802.3at task group and the TIA TR42.7 group can help to develop a better ampacity table.

Concerns with the overall direction and need for a code change

1. Collaboration with Standard Bodies
   The NFPA and the PoE standard bodies (IEEE and the TIA) should collaboratively work together on the recommendation going forward. As the PoE standard IEEE 802.3bt is not yet complete, there would be time for pro-active collaborative technical discussions.

2. Concern as to why the NFPA feels that there is a safety issue
   It is not clear nor has there been any information provided as to what constitutes a safety concern and how it is related to the power levels contained on communication cable that the IEEE, TIA and ISO standard bodies provide specifications for. More specifically, what
is the nature of the safety aspect and how does it manifest itself in the presence of cable.

(C) - Installations of New Cables.

New cables installed for carrying both communications and power, where the maximum adjusted ampacity of conductors exceed the values in Table 840.160(A), shall be Type CMP-LP, CMR-LP, or CM-LP, as applicable.

(D) - Using Cables Without the "LP" Marking for Supplying Premises Power and Communications.

New and existing cables without the "LP" marking shall be permitted to connect to communications equipment that supplies communications and power in accordance with the voltage and power limitations of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc, provided that the maximum current supplied by the power source is less than the adjusted ampacity of conductors in Table 840.160(A). For ambient temperatures other than 30°C (86°F) ampacity shall be permitted to be adjusted per Table 310.15(B)(2)(a).

Statement of Problem and Substantiation for Public Comment

The current proposed table 840.160A has been acknowledged as a placeholder and is not correct nor adequate for determination of current limitations on new or existing communications cabling. As of this date, assessment of temperature rise vs current in cabling installations is still under vigorous study, and industry agreement on these investigations and their results has not been achieved. New proposals to replace Table 840.160A with a more comprehensive table need to be adequately assessed by the cabling industry. This is not possible within the comment period. Preliminary results from the proprietary UL-Plastics industry study are not in agreement with data from other sources, nor my own careful measurements and calculations. The temperature rise of cables is highly dependent on installation conditions and must be addressed by installation guidelines and not through ampacity tables. The addition of a new LP class of cabling is premature, being submitted, A: before adequate assessment of the problem and optimal solutions have been studied, B: Without consideration of industry impact of such a requirement, and C: With no specification of the requirements for compliance to this new specification. I foresee at least two profound negative economic effects of this new cable classification: 1. Compliance to this requirement creates cables with larger conductors which increases cost. 2. Compliance to this requirement results in no change to existing cable constructions but adds cost through compliance testing. There are many unforeseen consequences of bringing communications cabling under the purview of electrical safety inspections that are too broad to be discussed in this comment. As has been mentioned in previous negative comments related to this section, a safety hazard has not been well established nor sufficiently studied by cabling standards bodies and lacks justification. Therefore this rulemaking is not only premature, but misguided. The proper venue to address the limitations of temperature rise power carrying communications cables is in the industry groups that create the cabling standards and installation methods for these products.
Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4564-NFPA 70-2015
Statement: The requirements proposed in the First Draft are outside the scope of Chapter 8 as well as the title and scope of Article 840. However, wording was added to direct the user to 725.144 for power delivery circuits that exceed 60 watts on communications cables.

Communications cables, in addition to carrying the communications circuit, shall also be permitted to carry circuits for powering communications equipment. The communications cables and the powering circuits shall comply with 840.160(A), (B), and (C), as applicable.

(A) . Power Limitations.

The power circuits shall comply with the requirements of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc.

Informational Note: The 100 VA (100 W) power source maximum nameplate rating in Chapter 9, Table 11(B) is the same as the maximum power rating for network-powered broadband communications systems Table 830.15, the communications industry standard in ATIS-0600337.2010, Requirements for Maximum Voltage, Current, and Power Levels in Network-Powered Transport Systems, and UL 60950.21, Information Technology Equipment Safety Part 21: Remote Power Feeding.

Table 840.160(A) Communications Conductor Ampacity Based on Copper Conductors at Ambient Temperature of 30°C (86°F), Conductor Temperature 60°C (140°F)

<table>
<thead>
<tr>
<th>Conductor Size (AWG)</th>
<th>Ampacity of Each Conductor in a Single 4-Pair Multipair Communications Cable Installed Separated from All Other Cables</th>
<th>Ampacity of Each Conductor in a Multipair Communications Cable when More Than One Cable Is Installed Together or the Multipair Cable Is Larger Than 4 Pairs</th>

<td>3.1</td>
<td>1.5</td>
</tr>
</tbody>
</table>

Informational Note: The conductor size of existing communications cable, including “category X” type cables, can be as small as 26 AWG.

(B) . Ampacity.

The maximum current carried by each communications conductor shall conform to Table 840.160(A).

Informational Note: The ampacity of the small wire gauges used in communications cables are not included in the ampacity tables in Article 310.

(C) . Installations of New Cables.

New cables installed for carrying both communications and power, where the maximum adjusted ampacity of conductors exceed the values in Table 840.160(A), shall be Type CMP-LP, CMR-LP, or CM-LP, as applicable.

(D) . Using Cables Without the "LP" Marking for Supplying Premises Power and Communications.

New and existing cables without the “LP” marking shall be permitted to connect to communications equipment that supplies communications and power in accordance with the voltage and power limitations of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc, provided that the maximum current supplied by the power source is less than the adjusted ampacity of conductors in Table 840.160(A). For ambient temperatures other than 30°C (86°F) ampacity shall be permitted to be adjusted per Table 310.15(B)(2)(a).

Statement of Problem and Substantiation for Public Comment

Statement of Problem and Substantiation:

For the following reasons, the IEEE 802.3 Working Group believes that this change to the code is premature and should be deferred to the 2020 code revision cycle. This delay should permit sufficient time for all interested and affected parties to review and comment.

1. Lack of LP Cable specification

At the date of the written comment submission deadline, 21 August 2015, the specifications and availability of the referenced LP cabling was not, to the best of our knowledge, publicly available. This fact alone makes it impossible to provide adequate technical review of this new type of cabling, thus effectively precluding public input.

2. Insufficient Technical Justification

At the date of the written comment submission deadline, 21 August 2015, no publicly-available technical data had been provided detailing the testing methodologies used as the basis for the proposed changes. There is insufficient technical justification provided for the change to require the use of LP cabling.

In addition, no technical data has been provided showing that when operating a communications circuit over a communications type cable under the established guidelines that a safety condition is created or exists.

This comment is being submitted on behalf of the IEEE 802.3 Ethernet Working Group.

Informational Note: The conductor size of existing communications cable, including "category X" type cables, can be as small as 26 AWG.

Statement of Problem and Substantiation for Public Comment

Aside from defining basic level of power requirements this section has no basis for specifying ampacities of the individual conductors. Table 840.160(A) and related references should be removed from the proposed code verbiage for the following reasons:

1) The Scope of Chapter 8 is Communication Circuits and Equipment and as such is primarily concerned with communication aspects of the equipment, equipment installation and caballing. The requirements for communication cables carrying power in conjunction with data are unique and is often limited to power levels far below those that would approach levels based on conductor gauge/ construction.

2) Given that the voltages and currents involved are SELV (Class 2/Limited-Power) there are no safety issues (risk of electric shock or risk of fire) associated with the use and installation of communication cables.

3) Transmitting power in conjunction with data over these cable assemblies has been going on for decades. To my knowledge there have not been any field reports regarding safety that would warrant introducing this ampacity table.

4) Ampacity table such as this belongs in Chapter 7 under 725 -Remote Control Signaling and Power-Limited Circuits, where standards for power being transmitted over these cables may in fact push the limit of the conductors themselves. However before any tables are added in the code careful review and study needs to be performed to account not only for cable construction but also for:
   a. Ambient temperatures around the cables
   b. Cable construction and number of active power carrying conductors
   c. Number of cables in a bundle of cables

Statement of Problem and Substantiation for Public Comment

There are certain issues with table 840.160(A):
1. The third column implies that the ampacity capacity is the same for any number of cables in a bundle, from 2 to the largest bundle that can be made. Experimental evidence has shown there is a larger temperature rise in a larger bundle.
2. There is a need for a bundle size limitation for new installations.
3. A 30 degree ambient temperature may not be high enough for modern data centers.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4564-NFPA 70-2015
Statement: The requirements proposed in the First Draft are outside the scope of Chapter 8 as well as the title and scope of Article 840. However, wording was added to direct the user to 725.144 for power delivery circuits that exceed 60 watts on communications cables.
Sections 840.160(C), 840.160(D)

(D) — Using Cables Without the “LP” Marking for Supplying Premises Power and Communications.

New and existing cables without the “LP” marking shall be permitted to connect to communications equipment that supplies communications and power in accordance with the voltage and power limitations of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc, provided that the maximum current supplied by the power source is less than the adjusted ampacity of conductors in Table 840.160(A).

(C) — Installations of New Cables.

New cables installed for carrying both communications and power, where the maximum adjusted ampacity of conductors exceed the values in Table 840.160(A), shall be Type CMP-LP, CMR-LP, or CM-LP as applicable.

Adjustment for ambient temperature.

For ambient temperatures other that 30°C (86°F) ampacity shall be permitted to be adjusted per Table 310.15(B)(2)(a).

Statement of Problem and Substantiation for Public Comment

If we understand the draft, a cable rated as xxx-LP would not be subject to table 840.160(A), but only to the power limitations in chapter 9. This will not provide a current limit for the cables, except as implied by the power limit and the voltage the power supply system uses, which can vary. Consequently, even though the ‘LP cables will have higher temperature rating, there is no assurance provided by this document that those cables will not be overheated.

The existing requirement (D) is largely redundant with (A) and (B) except for the temperature adjustment information. It seems to be intended to provide an exception to (C) but none is needed if (A) and (B) are met.

Committee Action: Rejected but see related SR
Resolution: SR-4564-NFPA 70-2015
Statement: The requirements proposed in the First Draft are outside the scope of Chapter 8 as well as the title and scope of Article 840. However, wording was added to direct the user to 725.144 for power delivery circuits that exceed 60 watts on communications cables.
840.170 Equipment and Cables.

Premises-powered broadband communications systems equipment and cables shall comply with 840.170(A) through (I).

(A) Network Terminal.
The network terminal and applicable grounding means shall be listed for application with premises-powered broadband communications systems.

Informational Note No. 2: There are no requirements on the network terminal and its grounding methodologies except for those covered by the listing of the product.

(B) Optical Fiber Cables.
Optical fiber cables shall be listed in accordance with 770.179(A) through (D) and shall be marked in accordance with Table 770.179.

(C) Communications Equipment.
Communications equipment shall be listed in accordance with 800.170. Premises communications wires and cables connecting to the network terminal shall be listed in accordance with 800.179.

(D) Cable Routing Assemblies and Communications Raceways
Cable routing assemblies and communications raceways shall be listed in accordance with 800.182.

(E) Premises Communications Wires and Cables.
Communications wires and cable shall be listed and marked in accordance with 800.179.

(F) Communications Limited-Power Cables
Communications limited-power cables shall be listed as suitable for carrying communications circuits and limited power circuits as specified in 840.160(C). Communications limited-power cable shall be marked CMP-LP, CMR-LP or CM-LP, as applicable.

(G) Premises Community Antenna Television (CATV) Circuits.
Premises community antenna television (CATV) coaxial cables connecting to the network terminal shall be listed in accordance with 820.179. Applicable grounding means shall be listed for application with premises-powered broadband communications systems.

(H) Power Source.
The power source for circuits intended to provide power over communications cables to remote equipment shall be limited in accordance with Table 11(B) in Chapter 9 for voltage sources up to 60 V dc and be listed as specified in 840.170(H)(1) or 840.170(H)(2):

(1) A power source shall be listed as specified in 725.121(A)(1), (A)(2), (A)(3), or (A)(4). The power sources shall not have the output connections paralleled or otherwise interconnected unless listed for such interconnection.

(2) A power source shall be listed as communications equipment for limited-power circuits.

Informational Note: One way to determine applicable requirements is to refer to ANSI/UL 60950, Safety of Information Technology Equipment; ANSI/UL 60950-1-2007, Standard for Safety of Information Technology Equipment-Safety-Part 1; or ANSI/UL 62368-1, Audio/Video, Information and Communication Technology Equipment-Part 1: Safety Requirements. Typically such circuits are used to interconnect equipment for the purpose of exchanging information (data).

(I) Accessory Equipment.
Communications accessory equipment and/or assemblies shall be listed for application with premises-powered communications systems.

Informational Note: One way to determine applicable requirements is to refer to UL 1863, Communications-Circuit Accessories.

Statement of Problem and Substantiation for Public Comment

This is an editorial Public Comment.

In 840.170(C), the recommended text corrects “ONT” to “network terminal”.
The recommended text deletes the redundant “Informational Note” in the informational note to 840.170(H).
The reference in 840.170(F) to the power limitations in 840.160(C) is incorrect. In FR 4643 the power limitations are in 840.160(A). The
recommended text corrects that error. The recommended text updates the issue of UL 60950 to 2014 in two places.

**Committee Action:** Rejected but see related SR
**Resolution:** SR-4565-NFPA 70-2015
**Statement:**
This revision corrects “ONT” to “network terminal” in (C).

The section for “Communications Limited-Power Cables” has been removed because the application was deleted in SR 4564.

This revision deletes the redundant “Informational Note” in the informational note to 840.170(G). The informational note references to UL standards have been updated to the current edition and ANSI added as applicable.
840.170. Equipment and Cables.

Premises-powered broadband communications systems equipment and cables shall comply with 840.170(A) through (I).

(A) Network Terminal.

The network terminal and applicable grounding means shall be listed for application with premises-powered broadband communications systems.

Informational Note No. 2: There are no requirements on the network terminal and its grounding methodologies except for those covered by the listing of the product.

(B) Optical Fiber Cables.

Optical fiber cables shall be listed in accordance with 770.179(A) through (D) and shall be marked in accordance with Table 770.179.

(C) Communications Equipment.

Communications equipment shall be listed in accordance with 800.170. Premises communications wires and cables connecting to the network terminal shall be listed in accordance with 800.179.

(D) Cable Routing Assemblies and Communications Raceways.

Cable routing assemblies and communications raceways shall be listed in accordance with 800.182.

(E) Premises Communications Wires and Cables.

Communications wires and cable shall be listed and marked in accordance with 800.179.

(F) Communications Limited-Power Cables.

Communications limited-power cables shall be listed as suitable for carrying communications circuits and limited power circuits as specified in 840.160(C). Communications limited-power cable shall be marked with the suffix "-LP(xxA)" where the xx is the current limit in amperes per conductor. For example, 1 ampere communications limited-power cable shall be marked CMP-LP (1A), CMR-LP (1A), CMG-LP(1A), or CM-LP (1A), as applicable.

Informational Note: LP cables are listed with current limits of 0.5, 0.6, 0.7, 0.8, 0.9, or 1.0 amperes per conductor. See UL444, the Standard for Communications Cables.

(G) Premises Community Antenna Television (CATV) Circuits.

Premises community antenna television (CATV) coaxial cables connecting to the network terminal shall be listed in accordance with 820.179. Applicable grounding means shall be listed for application with premises-powered broadband communications systems.

(H) Power Source.

The power source for circuits intended to provide power over communications cables to remote equipment shall be limited in accordance with Table 11(B) in Chapter 9 for voltage sources up to 60 V dc and be listed as specified in 840.170(H)(1) or 840.170(H)(2):

1. A power source shall be listed as specified in 725.121(A)(1), (A)(2), (A)(3), or (A)(4). The power sources shall not have the output connections paralleled or otherwise interconnected unless listed for such interconnection.

2. A power source shall be listed as communications equipment for limited-power circuits.

Informational Note: One way to determine applicable requirements is to refer to ANSI/UL 60950, Safety of Information Technology Equipment; ANSI/UL 60950-1-2007, Standard for Safety of Information Technology Equipment-Safety-Part 1; or ANSI/UL 60950-1-2007, Standard for Safety of Information Technology Equipment-Safety-Part 1: Safety Requirements. Typically, such circuits are used to interconnect equipment for the purpose of exchanging information (data).

(I) Accessory Equipment.

Communications accessory equipment and/or assemblies shall be listed for application with premises-powered communications systems.

Informational Note: One way to determine applicable requirements is to refer to UL 1863, Communications-Circuit Accessories.

Statement of Problem and Substantiation for Public Comment

Part of this Public Comment is editorial.

In 840.170(C), the recommended text corrects “ONT” to “network terminal”.

The recommended text deletes the redundant “Informational Note” in the informational note to 840.170(H).

The recommended text updates the issue of UL 60950 to 2014 in two places.

Part of this Public comment is technical.

The recommended text adds a Type CMG limited power cable. It was an oversight to omit Type CMG from the first draft.

The first draft provided for the listing of a limited power communications cable which would be suitable to install in worst-case installation conditions. Aside from having plenum, riser and general-purpose types, it was envisioned that there would be one LP cable for use in any bundle size. Although not explicitly stated in the Panel statement, a practical LP cable cannot have conductors larger than 22 AWG because 22 AWG is the largest conductor that will fit into a RJ 45 connector. Extensive testing at UL LLC has shown that, in many cases, large bundles of 4-pair cables with 22 AWG or smaller conductors exceed their temperature rating with all conductors carrying 1 amperes, which is well below the 1.67 ampere maximum current permitted in a 60 volt, 100 VA circuit. Accordingly, this Public Comment recommends that LP cables have a specified upper current limit. That will facilitate the use of small gauge conductors, 23 or 24 AWG for example, in low power systems used for communicating with, and powering of, communications equipment. It should be noted that wire gauge is not the only determinant of the thermal behavior of a cable; other aspects of the cable design are also important. Specifying the performance level of a cable, i.e.; capable of carrying 1 amperes in large enclosed cable bundle without exceeding its temperature rating, rather than specifying wire gauge and temperature rating will promote innovation in cable design.

See the attached UL Fact Finding Report on Power over Local Area Network Type Cables (4-Pair Data / Communications Cables) for supporting data.

UL has issued a Certification Requirement Decision to begin listing of LP cables.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4565-NFPA 70-2015
Statement: This revision corrects “ONT” to “network terminal” in (C).

The section for “Communications Limited-Power Cables” has been removed because the application was deleted in SR 4564.

This revision deletes the redundant “Informational Note” in the informational note to 840.170(G). The informational note references to UL standards have been updated to the current edition and ANSI added as applicable.
840.170 Equipment and Cables.
Premises-powered broadband communications systems equipment and cables shall comply with 840.170(A) through (I).

(A) Network Terminal.
The network terminal and applicable grounding means shall be listed for application with premises-powered broadband communications systems.

Informational Note No. 2: There are no requirements on the network terminal and its grounding methodologies except for those covered by the listing of the product.

(B) Optical Fiber Cables.
Optical fiber cables shall be listed in accordance with 770.179(A) through (D) and shall be marked in accordance with Table 770.179.

(C) Communications Equipment.
Communications equipment shall be listed in accordance with 800.170. Premises communications wires and cables connecting to the ONT shall be listed in accordance with 800.179.

(D) Cable Routing Assemblies and Communications Raceways
Cable routing assemblies and communications raceways shall be listed in accordance with 800.182.

(E) Premises Communications Wires and Cables.
Communications wires and cable shall be listed and marked in accordance with 800.179.

(F) Communications Limited-Power Cables
Communications limited-power cables shall be listed as suitable for carrying communications circuits and limited power circuits as specified in 840.160(C). Communications limited-power cable shall be marked CMP-LP, CMR-LP or CM-LP, as applicable.

Premises Community Antenna Television (CATV) Circuits.
Premises community antenna television (CATV) coaxial cables connecting to the network terminal shall be listed in accordance with 820.179. Applicable grounding means shall be listed for application with premises-powered broadband communications systems.

(H) Power Source.
The power source for circuits intended to provide power over communications cables to remote equipment shall be limited in accordance with Table 11(B) in Chapter 9 for voltage sources up to 60 V dc and be listed as specified in 840.170(H)(1) or 840.170(H)(2):

1. A power source shall be listed as specified in 725.121(A)(1), (A)(2), (A)(3), or (A)(4). The power sources shall not have the output connections paralleled or otherwise interconnected unless listed for such interconnection.

2. A power source shall be listed as communications equipment for limited-power circuits.

Informational Note: Informational Note: One way to determine applicable requirements is to refer to ANSI/UL 60950, Safety of Information Technology Equipment; ANSI/UL 60950-1-2007, Standard for Safety of Information Technology Equipment-Safety-Part 1; or ANSI/UL 62368-1, Audio/Video, information and Communication Technology Equipment-Part 1: Safety Requirements. Typically such circuits are used to interconnect equipment for the purpose of exchanging information (data).

(I) Accessory Equipment.
Communications accessory equipment and/or assemblies shall be listed for application with premises-powered communications systems.

Informational Note: One way to determine applicable requirements is to refer to UL 1863, Communications-Circuit Accessories.

Statement of Problem and Substantiation for Public Comment
CMP-LP, CMR-LP and CMX-LP cables are not defined, specified, tested and vetted for use in communications cables. This adds an unnecessary layer of confusion to the market and the industry which now has to determine when and where to use these cable types.
Until an known documented instance of a problem with existing cable types has been identified, there is no need for these cables.

**Resolution:** SR-4565-NFPA 70-2015  
**Statement:** This revision corrects “ONT” to “network terminal” in (C).

The section for “Communications Limited-Power Cables” has been removed because the application was deleted in SR 4564.

This revision deletes the redundant “Informational Note” in the informational note to 840.170(G). The informational note references to UL standards have been updated to the current edition and ANSI added as applicable.
840.170 Equipment and Cables.
Premises-powered broadband communications systems equipment and cables shall comply with 840.170(A) through (I).

(A) Network Terminal.
The network terminal and applicable grounding means shall be listed for application with premises-powered broadband communications systems.

Informational Note No. 2: There are no requirements on the network terminal and its grounding methodologies except for those covered by the listing of the product.

(B) Optical Fiber Cables.
Optical fiber cables shall be listed in accordance with 770.179(A) through (D) and shall be marked in accordance with Table 770.179.

(C) Communications Equipment.
Communications equipment shall be listed in accordance with 800.170. Premises communications wires and cables connecting to the network terminal shall be listed in accordance with 800.179.

(D) Cable Routing Assemblies and Communications Raceways.
Cable routing assemblies and communications raceways shall be listed in accordance with 800.182.

(E) Premises Communications Wires and Cables.
Communications wires and cable shall be listed and marked in accordance with 800.179.

(F) Communications Limited-Power Cables.
Communications limited-power cables shall be listed as suitable for carrying communications circuits and limited power circuits as specified in 840.160(C). Communications limited-power cable shall be marked CMP-LP, CMR-LP or CM-LP, as applicable.

(G) Premises Community Antenna Television (CATV) Circuits.
Premises community antenna television (CATV) coaxial cables connecting to the network terminal shall be listed in accordance with 820.179. Applicable grounding means shall be listed for application with premises-powered broadband communications systems.

(H) Power Source.
The power source for circuits intended to provide power over communications cables to remote equipment shall be limited in accordance with Table 11(B) in Chapter 9 for voltage sources up to 60 V dc and be listed as specified in 840.170(H)(1) or 840.170(H)(2):

1) A power source shall be listed as specified in 725.121(A)(1), (A)(2), (A)(3), or (A)(4). The power sources shall not have the output connections paralleled or otherwise interconnected unless listed for such interconnection.

2) A power source shall be listed as communications equipment for limited-power circuits.

Informational Note: Informational Note: One way to determine applicable requirements is to refer to ANSI/UL 60950, Safety of Information Technology Equipment; ANSI/UL 60950-1-2007, Standard for Safety of Information Technology Equipment-Safety-Part 1; or ANSI/UL 62368-1, Audio/Video, information and Communication Technology Equipment-Part 1: Safety Requirements. Typically such circuits are used to interconnect equipment for the purpose of exchanging information (data).

(I) Accessory Equipment.
Communications accessory equipment and/or assemblies shall be listed for application with premises-powered communications systems.

Informational Note: One way to determine applicable requirements is to refer to UL 1863, Communications-Circuit Accessories.
F - Electrical safety is extremely important and as such any action to reduce real risks is worthwhile to pursue. As such, we see that IEEE Power over DTE is a valuable technology due to the large number of safeguards that it mandates:

- Unless plugged in to a valid device, there is no voltage on the cable greater than a few volts, limited to very small power.
- During operation, both unplugging of the load, over-current and short-circuit are constantly monitored and action taken in case of an abnormal situation.
- PoE loads (PDs) are required to shut down in case the loop resistance of the cable exceeds the maximum supported.

We also note that there is a very large number of PoE ports operating in the field today. Across all these ports, we are not aware of a single instance of an unsafe situation arising due to the use of Power over Ethernet within the limits of IEEE 802.3.

The proposed addition to the NEC 4643-NFPA 70-2015 has been produced without consultation of the relevant group of PoE experts in the IEEE 802.3bt task group.

The comment also introduces a new form of cabling, for which no specification currently exists. This seems to preclude proper review of the proposed addition.

For this reason, and considering that there is no demonstrated incident of loss pressuring safety problem to address, this addition to the NEC should be postponed to the next revision of the Code. In this way, both BICSI and the cabling experts can contribute to a quality solution to be proposed for the 2020 version of NEC.

Consequently IEEE 802.3 Bicsi as well as many individual companies affected by these proposed changes, including Philips, will file a comment on the proposed draft. A comment by BICSI to the effect of postponing action to the 2020 Code cycle revision would seem appropriate.

BICSI is very interested in arranging collaboration between the NEC Panel 16, ISO/IEC/JTC 1/ SC 25/WG 3, TIA TR42 IEC TC 64, IEEE 802.3, HDBase-T, CCCA and BICSI Standards in this effort.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4565-NFPA 70-2015
Statement: This revision corrects "ONT" to "network terminal" in (C).

The section for "Communications Limited-Power Cables" has been removed because the application was deleted in SR 4564.

This revision deletes the redundant "Informational Note" in the informational note to 840.170(G). The informational note references to UL standards have been updated to the current edition and ANSI added as applicable.
(F) Communications Limited-Power Cables

Communications limited-power cables shall be listed as suitable for carrying communications circuits and limited power circuits as specified in 840.160(C). Communications limited-power cable shall be marked CMP-LP, CMR-LP, CMG-LP or CM-LP, as applicable.

Statement of Problem and Substantiation for Public Comment

CMG is also an accepted type of Communications Cable currently in the 2014 NEC and should also be included in the new "limited power" [-LP] type cables. I have also submitted PC# 171 to add "CMG-LP" to 840.160(C)

Submitter Information Verification

Submitter Full Name: GERALD DORNA
Organization: BELDEN WIRE CABLE CO

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4565-NFPA 70-2015
Statement: This revision corrects "ONT" to "network terminal" in (C).

The section for "Communications Limited-Power Cables" has been removed because the application was deleted in SR 4564.

This revision deletes the redundant "Informational Note" in the informational note to 840.170(G). The informational note references to UL standards have been updated to the current edition and ANSI added as applicable.
Article 90  Introduction

Sections 90.1, 90.2, 90.3, 90.4, 90.5, 90.6, 90.7, 90.8, 90.9

90.1 Purpose.

(A) Practical Safeguarding.

The purpose of this Code is the practical safeguarding of persons and property from hazards arising from the use of electricity. This Code is not intended as a design specification or an instruction manual for untrained persons.

(B) Adequacy.

This Code contains provisions that are considered necessary for safety. Compliance therewith and proper maintenance result in an installation that is essentially free from hazard but not necessarily efficient, convenient, or adequate for good service or future expansion of electrical use.

Informational Note: Hazards often occur because of overloading of wiring systems by methods or usage not in conformity with this Code. This occurs because initial wiring did not provide for increases in the use of electricity. An initial adequate installation and reasonable provisions for system changes provide for future increases in the use of electricity.

(C) Relation to Other International Standards.

The requirements in this Code address the fundamental principles of protection for safety contained in Section 131 of International Electrotechnical Commission Standard 60364-1, Electrical Installations of Buildings.

Informational Note: IEC 60364-1, Section 131, contains fundamental principles of protection for safety that encompass protection against electric shock, protection against thermal effects, protection against overcurrent, protection against fault currents, and protection against overvoltage. All of these potential hazards are addressed by the requirements in this Code.

90.2 Scope.

(A) Covered.

This Code covers the installation and removal of electrical conductors, equipment, and raceways; signaling and communications conductors, equipment, and raceways; and optical fiber cables and raceways for the following:

(1) Public and private premises, including buildings, structures, mobile homes, recreational vehicles, and floating buildings

(2) Yards, lots, parking lots, carnivals, and industrial substations

(3) Installations of conductors and equipment that connect to the supply of electricity

(4) Installations used by the electric utility, such as office buildings, warehouses, garages, machine shops, and recreational buildings, that are not an integral part of a generating plant, substation, or control center
(B) Not Covered.

This Code does not cover the following:

1. Installations in ships, watercraft other than floating buildings, railway rolling stock, aircraft, or automotive vehicles other than mobile homes and recreational vehicles
   Informational Note: Although the scope of this Code indicates that the Code does not cover installations in ships, portions of this Code are incorporated by reference into Title 46, Code of Federal Regulations, Parts 110–113.

2. Installations underground in mines and self-propelled mobile surface mining machinery and its attendant electrical trailing cable

3. Installations of railways for generation, transformation, transmission, energy storage, or distribution of power used exclusively for operation of rolling stock or installations used exclusively for signaling and communications purposes

4. Installations of communications equipment under the exclusive control of communications utilities located outdoors or in building spaces used exclusively for such installations

5. Installations under the exclusive control of an electric utility where such installations
   a. Consist of service drops or service laterals, and associated metering, or
   b. Are on property owned or leased by the electric utility for the purpose of communications, metering, generation, control, transformation, transmission, energy storage, or distribution of electric energy, or
   c. Are located in legally established easements or rights-of-way, or
   d. Are located by other written agreements either designated by or recognized by public service commissions, utility commissions, or other regulatory agencies having jurisdiction for such installations. These written agreements shall be limited to installations for the purpose of communications, metering, generation, control, transformation, transmission, energy storage, or distribution of electric energy where legally established easements or rights-of-way cannot be obtained. These installations shall be limited to federal lands, Native American reservations through the U.S. Department of the Interior Bureau of Indian Affairs, military bases, lands controlled by port authorities and state agencies and departments, and lands owned by railroads.

   Informational Note to (4) and (5): Examples of utilities may include those entities that are typically designated or recognized by governmental law or regulation by public service/utility commissions and that install, operate, and maintain electric supply (such as generation, transmission, or distribution systems) or communications systems (such as telephone, CATV, Internet, satellite, or data services). Utilities may be subject to compliance with codes and standards covering their regulated activities as adopted under governmental law or regulation. Additional information can be found through consultation with the appropriate governmental bodies, such as state regulatory commissions, the Federal Energy Regulatory Commission, and the Federal Communications Commission.

(C) Special Permission.

The authority having jurisdiction for enforcing this Code may grant exception for the installation of conductors and equipment that are not under the exclusive control of the electric utilities and are used to connect the electric utility supply system to the service conductors of the premises served, provided such installations are outside a building or structure, or terminate inside at a readily accessible location nearest the point of entrance of the service conductors.
90.3 Code Arrangement.

This Code is divided into the introduction and nine chapters, as shown in Figure 90.3. Chapters 1, 2, 3, and 4 apply generally. Chapters 5, 6, and 7 apply to special occupancies, special equipment, or other special conditions, and may supplement or modify the requirements in Chapters 1 through 7.

Chapter 8 covers communications systems and is not subject to the requirements of Chapters 1 through 7 except where the requirements are specifically referenced in Chapter 8.

Chapter 9 consists of tables that are applicable as referenced.

Informative annexes are not part of the requirements of this Code but are included for informational purposes only.

Figure 90.3 Code Arrangement.

90.4 Enforcement.

This Code is intended to be suitable for mandatory application by governmental bodies that exercise legal jurisdiction over electrical installations, including signaling and communications systems, and for use by insurance inspectors. The authority having jurisdiction for enforcement of the Code has the responsibility for making interpretations of the rules, for deciding on the approval of equipment and materials, and for granting the special permission contemplated in a number of the rules.

By special permission, the authority having jurisdiction may waive specific requirements in this Code or permit alternative methods, where it is assured that equivalent objectives can be achieved by establishing and maintaining effective safety.

This Code may require new products, constructions, or materials that may not yet be available at the time the Code is adopted. In such event, the authority having jurisdiction may permit the use of the products, constructions, or materials that comply with the most recent previous edition of this Code adopted by the jurisdiction.

90.5 Mandatory Rules, Permissive Rules, and Explanatory Material.

(A) Mandatory Rules.

Mandatory rules of this Code are those that identify actions that are specifically required or prohibited and are characterized by the use of the terms shall or shall not.

(B) Permissive Rules.

Permissive rules of this Code are those that identify actions that are allowed but not required, are normally used to describe options or alternative methods, and are characterized by the use of the terms shall be permitted or shall not be required.

(C) Explanatory Material.

Explanatory material, such as references to other standards, references to related sections of this Code, or information related to a Code rule, is included in this Code in the form of informational notes. Such notes are informational only and are not enforceable as requirements of this Code.

Brackets containing section references to another NFPA document are for informational purposes only and are provided as a guide to indicate the source of the extracted text. These bracketed references immediately follow the extracted text.

Informational Note: The format and language used in this Code follows guidelines established by NFPA and published in the NEC Style Manual. Copies of this manual can be obtained from NFPA.

(D) Informative Annexes.

Nonmandatory information relative to the use of the NEC is provided in informative annexes. Informative annexes are not part of the enforceable requirements of the NEC but are included for information purposes only.
90.6  Formal Interpretations.
To promote uniformity of interpretation and application of the provisions of this Code, formal interpretation procedures have been established and are found in the NFPA Regulations Governing Committee Projects.

90.7  Examination of Equipment for Safety.
For specific items of equipment and materials referred to in this Code, examinations for safety made under standard conditions provide a basis for approval where the record is made generally available through promulgation by organizations properly equipped and qualified for experimental testing, inspections of the run of goods at factories, and service-value determination through field inspections. This avoids the necessity for repetition of examinations by different examiners, frequently with inadequate facilities for such work, and the confusion that would result from conflicting reports on the suitability of devices and materials examined for a given purpose.

It is the intent of this Code that factory-installed internal wiring or the construction of equipment need not be inspected at the time of installation of the equipment, except to detect alterations or damage, if the equipment has been listed by a qualified electrical testing laboratory that is recognized as having the facilities described in the preceding paragraph and that requires suitability for installation in accordance with this Code.

Informational Note No. 1: See requirements in 110.3.
Informational Note No. 2: Listed is defined in Article 100.
Informational Note No. 3: Informative Annex A contains an informative list of product safety standards for electrical equipment.

90.8  Wiring Planning.
(A) Future Expansion and Convenience.
Plans and specifications that provide ample space in raceways, spare raceways, and additional spaces allow for future increases in electric power and communications circuits. Distribution centers located in readily accessible locations provide convenience and safety of operation.

(B) Number of Circuits in Enclosures.
It is elsewhere provided in this Code that the number of circuits confined in a single enclosure be varyingly restricted. Limiting the number of circuits in a single enclosure minimizes the effects from a short circuit or ground fault.

90.9  Units of Measurement.
(A) Measurement System of Preference.
For the purpose of this Code, metric units of measurement are in accordance with the modernized metric system known as the International System of Units (SI).

(B) Dual System of Units.
SI units shall appear first, and inch-pound units shall immediately follow in parentheses. Conversion from inch-pound units to SI units shall be based on hard conversion except as provided in 90.9(C).

(C) Permitted Uses of Soft Conversion.
The cases given in 90.9(C)(1) through (C)(4) shall not be required to use hard conversion and shall be permitted to use soft conversion.

(1) Trade Sizes.
Where the actual measured size of a product is not the same as the nominal size, trade size designators shall be used rather than dimensions. Trade practices shall be followed in all cases.

(2) Extracted Material.
Where material is extracted from another standard, the context of the original material shall not be compromised or violated. Any editing of the extracted text shall be confined to making the style consistent with that of the NEC.

(3) Industry Practice.
Where industry practice is to express units in inch-pound units, the inclusion of SI units shall not be required.

(4) Safety.
Where a negative impact on safety would result, soft conversion shall be used.

(D) Compliance.
Conversion from inch-pound units to SI units shall be permitted to be an approximate conversion. Compliance with the numbers shown in either the SI system or the inch-pound system shall constitute compliance with this Code.

Informational Note No. 1: Hard conversion is considered a change in dimensions or properties of an item into new sizes that might or might not be interchangeable with the sizes used in the original measurement. Soft conversion is considered a direct mathematical conversion and involves a change in the description of an existing measurement but not in the actual dimension.

Statement of Problem and Substantiation for Public Comment

Public Input 1953 should have been accepted. There was no substantiation because it is a usability issue. What I proposed is a basic mathematical principal, it isn't mine to substantiate.

Submittal Date: Fri Sep 25 16:29:40 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The proposed text does not add clarity to the application of this requirement. There is not adequate substantiation to support the need to add the proposed text to Article 90. Duplication of section 220.5(B) is unnecessary.
Public Comment No. 123-NFPA 70-2015 [Section No. 90.2(B)]

(B) Not Covered.
This Code does not cover the following:

(1) Installations in ships, watercraft other than floating buildings, railway rolling stock, aircraft, or automotive vehicles other than mobile homes and recreational vehicles

   Informational Note: Although the scope of this Code indicates that the Code does not cover installations in ships, portions of this Code are incorporated by reference into Title 46, Code of Federal Regulations, Parts 110–113.

(2) Installations underground in mines and self-propelled mobile surface mining machinery and its attendant electrical trailing cable

(3) Installations of railways for generation, transformation, transmission, energy storage, or distribution of power used exclusively for operation of rolling stock or installations used exclusively for signaling and communications purposes

(4) Installations of communications equipment under the exclusive control of communications utilities located outdoors or in building spaces used exclusively for such installations

(5) Installations under the exclusive control of an electric utility where such the electric utility installs, maintains, and repairs such installations

   (6) Consist of service drops or service laterals, and associated metering and meter-mounted transfer switches, or

   (7) Are on property owned or leased by the electric utility for the purpose of communications, metering, generation, control, transformation, transmission, energy storage, or distribution of electric energy, or

   (8) Are located in legally established easements or rights-of-way, or

   (9) Are located by other written agreements either designated by or recognized by public service commissions, utility commissions, or other regulatory agencies having jurisdiction for such installations. These written agreements shall be limited to installations for the purpose of communications, metering, generation, control, transformation, transmission, energy storage, or distribution of electric energy where legally established easements or rights-of-way cannot be obtained. These installations shall be limited to federal lands, Native American reservations through the U.S. Department of the Interior Bureau of Indian Affairs, military bases, lands controlled by port authorities and state agencies and departments, and lands owned by railroads.

Informational Note to (4) and (5): Examples of utilities may include those entities that are typically designated or recognized by governmental law or regulation by public service/utility commissions and that install, operate, and maintain electric supply (such as generation, transmission, or distribution systems) or communications systems (such as telephone, CATV, Internet, satellite, or data services). Utilities may be subject to compliance with codes and standards covering their regulated activities as adopted under governmental law or regulation. Additional information can be found through consultation with the appropriate governmental bodies, such as state regulatory commissions, the Federal Energy Regulatory Commission, and the Federal Communications Commission.

Statement of Problem and Substantiation for Public Comment

The UL 1008M standard for meter-mounted transfer switches was recently amended to allow for the connection of a permanently installed generator. The scope of this UL standard, in Section 1.3 clearly states that these types of devices be under the exclusive control of the serving utility, and are not under the purview of the NEC. The term "exclusive control" needs to be defined by the code as the party who is responsible for the installation, maintaining, servicing, and repairing of the equipment in question. Utility installation are not under the purview of the NEC, however if the device was installed by an electrical contractor, the installation would be under the purview of the NEC and the UL listing of the device would be violated. The proposed language would bring clarity that these types of devices are UL listed as utility equipment to be installed by the utility, and under the utilities exclusive control, and not as listed electrical equipment that can be installed by an electrical contractor.

UL 1008M TRANSFER SWITCH EQUIPMENT, METER MOUNTED

1 Scope

1.1 These requirements cover automatic and non-automatic (manual) transfer switch equipment, operating at 600 V ac less, and intended for installation in a utility meter base, in ordinary locations only.

1.2 These devices are intended for use in optional standby systems only, and are intended for cord connection of a portable generator to power a premise wiring system, where the neutral (grounded circuit conductor) of the generator is not bonded to ground or the generator frame. Bonding of the neutral (grounded circuit conductor) to ground will occur within the meter base. These devices are not...
intended for use in Emergency or Legally Required Standby Systems.

1.3 The installation of these devices is intended to be under the exclusive control of the serving utility, and these are not considered under the purview of the National Electrical Code, NFPA 70.

1.4 An automatic transfer switch as covered by these requirements is a device that automatically transfers a common load from a normal supply to an alternate supply in the event of failure of the normal supply, and automatically returns the load to the normal supply when the normal supply is restored. An automatic transfer switch may be provided with a logic control circuit that inhibits automatic operation of the device from either a normal to an alternate supply, or from an alternate to a normal supply when the switch reverts to automatic operation upon loss of power to the load.

1.5 A non-automatic transfer switch as covered by these requirements is a device, operated manually by a physical action, or electrically by a remote control, for transferring a common load between a normal and alternate supply.

1.6 A transfer switch may incorporate overcurrent protection for the main power circuits.

1.7 These requirements only cover transfer switches which are completely enclosed when installed in a meter base in conjunction with the electrical utility meter.

1.8 Transfer switches are rated in amperes and are considered to be acceptable for total system transfer, which includes control of motors, electric-heating loads, and transformer loads.

Submitter Information Verification

Submitter Full Name: BRIAN BAUGHMAN  
Organization: GENERAC POWER SYSTEMS  
Street Address:  
City:  
State:  
Zip:  
Submittal Date: Mon Jul 06 11:59:03 EDT 2015

Committee Statement

Committee Action: Rejected  
Resolution: The proposed language does not enhance clarity or usability of what is not covered. It is not necessary to further clarify what “exclusive control” means.
Public Comment No. 1505-NFPA 70-2015 [Section No. 90.2(A)]

(A) Covered.

This Code covers the installation and removal of electrical conductors, equipment, and raceways; signaling and communications conductors, equipment, and raceways; and optical fiber cables and raceways for the following:

(1) Public and private premises, including buildings, structures, mobile homes, recreational vehicles, and floating buildings
(2) Yards, lots, parking lots, carnivals, and industrial substations
(3) Installations of conductors and equipment that connect to the supply of electricity
(4) Installations used by the electric utility, such as office buildings, warehouses, garages, machine shops, and recreational buildings, that are not an integral part of a generating plant, substation, or control center

Statement of Problem and Substantiation for Public Comment

FR-1 should not have been accepted. While the Code covers the removal of wiring, these requirements are limited to only a few sections. The addition of "removal" to 90.2(A) may have unintended consequences and be misinterpreted to include more widespread removal of conductors, equipment and raceway than the sections specifically addressed. "Installation" is used in a broad sense and a laundry list of what aspects of installations the Code covers is not necessary.

Committee Statement

Committee Action: Rejected
Resolution: The committee reaffirms that "removal" is within the scope of the NEC. There are numerous requirements requiring removal of electrical conductors and equipment.
Public Comment No. 1882-NFPA 70-2015 [Section No. 90.2(B)]

(B) Not Covered.
This Code does not cover the following:

1. Installations in ships, watercraft other than floating buildings, railway rolling stock, aircraft, or automotive vehicles other than mobile homes and recreational vehicles
   Informational Note: Although the scope of this Code indicates that the Code does not cover installations in ships, portions of this Code are incorporated by reference into Title 46, Code of Federal Regulations, Parts 110–113.

2. Installations underground in mines and self-propelled mobile surface mining machinery and its attendant electrical trailing cable

3. Installations of railways for generation, transformation, transmission, energy storage, or distribution of power used exclusively for operation of rolling stock or installations used exclusively for signaling and communications purposes

4. Installations of communications equipment under the exclusive control of communications utilities located outdoors or in building spaces used exclusively for such installations

5. Installations under the exclusive control of an electric utility where such installations
   a. Consist of service drops or service laterals, and associated metering, or
   b. Are on property owned or leased by the electric utility for the purpose of communications, metering, generation, control, transformation, transmission, energy storage, or distribution of electric energy, or
   c. Are located in legally established easements or rights-of-way, or
   d. Are located by other written agreements either designated by or recognized by public service commissions, utility commissions, or other regulatory agencies having jurisdiction for such installations. These written agreements shall be limited to installations for the purpose of communications, metering, generation, control, transformation, transmission, energy storage, or distribution of electric energy where legally established easements or rights-of-way cannot be obtained. These installations shall be limited to federal lands, Native American reservations through the U.S. Department of the Interior Bureau of Indian Affairs, military bases, lands controlled by port authorities and state agencies and departments, and lands owned by railroads.

   Informational Note to (4) and (5): Examples of utilities may include those entities that are typically designated or recognized by governmental law or regulation by public service/utility commissions and that install, operate, and maintain electric supply (such as generation, transformation, or distribution systems) or communications systems (such as telephone, CATV, Internet, satellite, or data services). Utilities may be subject to compliance with codes and standards covering their regulated activities as adopted under governmental law or regulation. Additional information can be found through consultation with the appropriate governmental bodies, such as state regulatory commissions, the Federal Energy Regulatory Commission, and the Federal Communications Commission.

Statement of Problem and Substantiation for Public Comment

The Correlating Committee directs that further consideration be given to the comments expressed in voting on FR 2. For information, definitions related to "energy storage" are contained in FR 3662.

Submitter Full Name: CC on NEC-AAC
Organization: NFPA
Street Address:
City:
State:
Zip:
Submittal Date: Tue Sep 29 12:47:44 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: CMP1 reviewed comments under FR-2 and "energy storage" is the correct term.
90.7 Examination of Equipment for Safety.

For specific items of equipment and materials referred to in this Code, examinations for safety made under standard conditions provide a basis for approval where the record is made generally available through promulgation by organizations properly equipped and qualified for experimental testing, inspections of the run of goods at factories, and service-value determination through field inspections. This avoids the necessity for repetition of examinations by different examiners, frequently with inadequate facilities for such work, and the confusion that would result from conflicting reports on the suitability of devices and materials examined for a given purpose.

It is the intent of this Code that factory-installed internal wiring or the construction of equipment need not be inspected at the time of installation of the equipment, except to detect alterations or damage, if the equipment has been listed by a qualified electrical testing laboratory that is recognized as having the facilities described in the preceding paragraph and that requires suitability for installation in accordance with this Code. Suitability shall be determined by application of requirements which are compatible with this Code.

Informational Note No. 1: See requirements in 110.3.
Informational Note No. 2: Listed is defined in Article 100.
Informational Note No. 3: Informative Annex A contains an informative list of product safety standards for electrical equipment which are compatible with this Code.

Statement of Problem and Substantiation for Public Comment

Equipment standards are developed in coordination with installation Codes to ensure safety and compatibility. Product standards which do not specifically anticipate compliance or coordination with the NEC present installation problems (such as specifying metric conductor sizes), non-compliance issues (with Code specific construction requirements) and safety concerns (such as overcurrent protection schemes which are incompatible with the NEC). Product standards which are developed to align with the NEC identify this intention in the scope of each Standard, and unless additional evaluation is performed, only these products can be assured to meet NEC requirements.

Informative Annex A, Product Safety Standards

Informative Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only.

This informative annex provides a list of product safety standards used for product listing where that listing is required by this Code. It is recognized that this list is current at the time of publication but that new standards or modifications to existing standards can occur at any time while this edition of the Code is in effect.

This informative annex does not form a mandatory part of the requirements of this Code but is intended only to provide Code users with informational guidance about the product characteristics about which Code requirements have been based.

### Committee Statement

**Committee Action:** Rejected but see related SR  
**Resolution:** SR-4-NFPA 70-2015  
**Statement:** The word "potentially" was removed from a document title to match current title of ANSI/ISA 12.27.01.
Typical Applications Covered by Tables.

Typical ampacities for conductors rated 0 through 2000 volts are shown in Table B.310.15(B)(2)(1) through Table B.310.15(B)(2)(10). Table B.310.15(B)(2)(11) provides the adjustment factors for more than three current-carrying conductors in a raceway or cable with load diversity. Underground electrical duct bank configurations, as detailed in Figure B.310.15(B)(2)(3), Figure B.310.15(B)(2)(4), and Figure B.310.15(B)(2)(5), are utilized for conductors rated 0 through 5000 volts. In Figure B.310.15(B)(2)(2) through Figure B.310.15(B)(2)(5), where adjacent duct banks are used, a separation of 1.5 m (5 ft) between the centerlines of the closest ducts in each bank or 1.2 m (4 ft) between the extremities of the concrete envelopes is sufficient to prevent derating of the conductors due to mutual heating. These ampacities were calculated as detailed in the basic ampacity paper, AIEE Paper 57-660, *The Calculation of the Temperature Rise and Load Capability of Cable Systems*, by J. H. Neher and M. H. McGrath. For additional information concerning the application of these ampacities, see IEEE/CEA Standard S-135/P-46426, *Power Cable Ampacities*, and IEEE Standard IEEE STD 835-1994, *Standard Power Cable Ampacity Tables*.

Typical values of thermal resistivity (Rho) are as follows:

- Average soil (90 percent of USA) = 90
- Concrete = 55
- Damp soil (coastal areas, high water table) = 60
- Paper insulation = 550
- Polyethylene (PE) = 450
- Polyvinyl chloride (PVC) = 650
- Rubber and rubber-like = 500
- Very dry soil (rocky or sandy) = 120

*Thermal resistivity*, as used in this informative annex, refers to the heat transfer capability through a substance by conduction. It is the reciprocal of thermal conductivity and is normally expressed in the units°C-cm/watt. For additional information on determining soil thermal resistivity (Rho), see ANSI/IEEE Standard IEEE STD 442-1996, *Guide for Soil Thermal Resistivity Measurements*.

Statement of Problem and Substantiation for Public Comment

Removed superseded national standards.

Committee Statement

Committee Action: Accepted
Resolution: SR-1501-NFPA 70-2015
Statement: Removed superseded national standards.
Public Comment No. 309-NFPA 70-2015 [Definition: Feeder Short-Circuit and Ground-Fault Protection]

Feeder Short-Circuit and Ground-Fault Protection

The rating of the feeder protective device is based on the sum of the largest branch-circuit protective device for the specific device protecting the feeder (example is 110 A) plus the sum of the full-load currents of the other motors, or 110 A \(+\) 40 A \(=\) 190 A. The nearest standard non time delay fuse that does not exceed this value is 175 A [see 240.6 and 430.62(A)].

Feeder Short-Circuit and Ground-Fault Protection Using Inverse Time Circuit Breaker.

The rating of the feeder protective device is based on the sum of the largest branch-circuit protective device for the specific device protecting the feeder, plus the sum of the full load currents of the other motors. 250\% \times 34 \text{ Amps} = 85 \text{ A}. The next larger standard size is 90 A, plus the sum of the full load currents of the other motors or 90 A plus 40 A plus 40 A = 170 A. The nearest standard breaker that does not exceed this value is 150 A [see 240.6, 430.62(A)].

Statement of Problem and Substantiation for Public Comment

This PI was misplaced and sent to the wrong panel, then to the wrong section in 430.62. CMP 11 rightfully rejected it as it is informative in nature an belongs in the Annex. The original PI was submitted as modifying the annex example D8 due to the considerable confusion that exists as to how to calculate the protection of the feeder. This additional example makes the intent clear and prevents feeders from being unprotected by oversizing the short circuit ground fault protection of the feeder. The existing example uses the same kind of branch circuit protection as the feeder, the submitted text provides an additional example to make certain that the "(based on the maximum permitted value for the specific type of overcurrent protective device...)" in 430.62 is in regard to the device protecting the feeder and not one of the branch circuits. This phrase was added to the 1993 code due to the confusion and used a breaker example for substantiation and was unanimously affirmative by the panel in the ROC stage (See11-30-(430.62 (a)) Log 2416, page 451). By including an actual breaker example, this eliminates confusion.

Please note the terra-view software did not allow a plus sign to be added in the formula for the breaker, and the word "plus" was used instead to reduce any misunderstanding.

Submitter Information Verification

Submitter Full Name: JOHN MCCAMISH
Organization: NECA IBEW ELECTRICAL TRAINING
Street Address:
City:
State:
Zip:
Submittal Date: Tue Jul 28 13:30:59 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-3007-NFPA 70-2015
Statement: The changes to the example clarify the application method.
Feeder Short-Circuit and Ground-Fault Protection

(a) Example using Nontime delay fuse. The rating of the feeder protective device is based on the sum of the largest branch-circuit protective device \((\text{example is } 110 \text{ A})\) plus for the specific type of device protecting the feeder, \(300\% \times 34 \text{ A} = 110 \text{ A}\). Plus, the sum of the full-load currents of the other motors, or \(110 \text{ A } + 40 \text{ A } + 40 \text{ A} = 190 \text{ A}\). The nearest standard fuse that does not exceed this value is 175 A [see 240.6 and 430.62(A)].

(b) Example using Inverse Time Circuit Breaker. The largest branch-circuit protective device for the specific type of device protecting the feeder, \(250\% \times 34 \text{ A} = 85\). The next larger standard size is 90 A. Plus the sum of the full-load currents of the other motors, or 90 A (plus sign) 40 A (plus sign) 40 A = 170 A. The nearest standard breaker that does not exceed this value is 150 A. (see 240.6 and 430.62(A)).

Statement of Problem and Substantiation for Public Comment

The original Public Input 440 was incorrectly identified as a definition and was not directed to CMP-11 for a proposed change to Annex D: Examples, Example D8 as intended by the author. The working in 430.62 is clear but Annex example D8 relating to motor feeder short-circuit and ground-fault protection calculations did not accurately reflect the requirements of 430.62. The key being the inclusion of "for the specific device protecting the feeder" to correspond with 430.62. The additional example further clarifies the requirement where a different type of protective device is used.

Submittal Date: Fri Sep 04 19:38:49 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-3007-NFPA 70-2015
Statement: The changes to the example clarify the application method.
Public Comment No. 1049-NFPA 70-2015 [ Definition: Energy Storage System (ESS). [Excluding any Sub... ]

A device or more than one device assembled together capable of storing energy for use at a future time. ESS(s) includes can include, but is not limited to electrochemical storage devices (e.g., batteries), flow batteries, capacitors, and kinetic energy devices (e.g., flywheels and compressed air). These systems can have ac or dc output for utilization and can include inverters and converters to change stored energy into electrical energy.

Statement of Problem and Substantiation for Public Comment

As written, the 2nd sentence of the definition implies that an ESS always has the items that are listed (i.e., electrochemical storage devices, flow batteries, capacitors, and kinetic energy devices), which contradicts the previous sentence. This PC changes "includes" to "can include" to harmonize the two sentences.

Public Comment No. 1708-NFPA 70-2015 [ New Part after I. ]

694 - Wind Turbines Systems - Working Clearances
Working space shall be provided for electrical cabinets and other electrical equipment in accordance with 110.26(A).

For large wind turbines permitting entry of service personnel, where space constraints exist and there is a necessity for performing diagnostic work on energized equipment (for example in the Nacelle), working clearances shall comply with following table up to 1,000:

<table>
<thead>
<tr>
<th>Nominal voltage to ground</th>
<th>Condition 1</th>
<th>Condition 2</th>
<th>Condition 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-150</td>
<td>900 mm (3 ft)</td>
<td>900 mm (3 ft)</td>
<td>900 mm (3 ft)</td>
</tr>
<tr>
<td>151-1,000</td>
<td>900 (3 ft)</td>
<td>1.0 m (3 ft 6 in)</td>
<td>1.2 m (4 ft)</td>
</tr>
</tbody>
</table>

Note: Conditions are defined in accordance with section 110.26, extending the values from 600V to 1,000V

Conditions of maintenance and supervision shall ensure that only qualified persons examine, adjust, service, and maintain the equipment.

Statement of Problem and Substantiation for Public Comment
Working spaces in large wind turbines in the nacelle and hub where space is limited, and considering UL 6141 with consideration to extended voltage range to 1000V

City:
State:
Zip:
Submittal Date: Fri Sep 25 17:01:34 EDT 2015

Committee Statement
Committee Action: Rejected but see related SR
Resolution: SR-921-NFPA 70-2015
Statement:
The 2017 first draft changed Table 110.26(A)(1) to reflect the change throughout the Code from 600 to 1000 V. A third line was added to the table:

601–1000 V: 900 mm (3 ft) 1.2 m (4 ft) 1.5 m (5 ft)

Many wind turbines operate at 690 Vac and in the past took spacings requirements from the 2014 Table 110.26(A)(1) line 2. The new requirements for greater than 600 V use the 2014 values from Table 110.34(A) line 1 (601-2500V).

Requirements for 2500 V are a major change for systems that may operate at 690 V, and 30 cm of additional space is very difficult to implement in existing designs, and especially for wind turbine nacelles.

Access using reduced spacings is limited to qualified personnel.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-3914-NFPA 70-2015
Statement: Revisions were made to reference current editions of NFPA documents 77, 91 and 701. Editorial revisions were made to extracted text to comply with the NEC Style Manual.
Part III. Electrochemical Energy Storage Systems

Part III of this article applies to ESSs that are comprised of sealed and non-sealed cells or batteries or system modules that are comprised of multiple sealed cells or batteries that are not components within a listed product.

Informational Note: Energy storage devices, such as batteries, that are integrated into a larger piece of listed equipment, such as an uninterruptible power supply (UPS), are not covered by this section.

Statement of Problem and Substantiation for Public Comment

Article 706 does not put any boundaries on the size of an ESS. It is not the intent that Article 706 should cover items such as a single-phase UPS system or an emergency lighting chassis. This PC clarifies that a listed product, such as a UPS system or a piece of medical equipment, that happens to contain a battery or a string of batteries, would not be considered as an Energy Storage System that is covered by this section.

This Public Comment also adds an informational note to clarify the intent of the added text.

Part IV. Microgrid (Intentionally Islanded and Stand-Alone) Systems

Statement of Problem and Substantiation for Public Comment

This heading should be modified as:
1/ part of this section should move to Art 710 [proposed] Standalone Systems, as recommended by TCC, and thus "Standalone" is removed from heading/
Standalone systems DOES NOT belong in Interconnected Systems! They are fundamental opposites.
Creation of Article 710 standalone systems [new] should be referred to a task group prior to the SD meeting.

2/ The common and now widely used term for intentional island systems is now "microgrids". The former term (used in IEEE1547.4 is now superseded. See for example IEEE P2030.7 and 2030.8.

3/ intentional island systems should be changed to microgrid (intentional island) systems throughout this section (i.e. all sub-paragraphs below this heading.
A task group should be assigned to this part of Article 705.

Submittal Date: Tue Sep 29 09:58:45 EDT 2015

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4226-NFPA 70-2015
Statement: Change to the Title of Part VI. is required to better cover First Draft changes made to sections 520.71, 520.72, 520.73, and 520.74.
Part IV. Listing Requirements

725.170 Listing and Marking of Equipment. The listed power source for circuits intended to provide power and data over Class 2 cables to remote equipment shall be as specified in 725.121(A)(1), (A)(2), (A)(3), or (A)(4). The power sources shall not have the output connections paralleled or otherwise interconnected unless listed for such interconnection. Powered devices connected to a circuit supplying data and power shall be listed. Nameplate ratings shall include rated voltage and current available at the output of the listed power source equipment.

Statement of Problem and Substantiation for Public Comment

This Public Comment is one of a series on cable heating due to the transmission of power and data using cables that are typically bundled, and in support of the Public Comment to resolved Public Input 1837.

Presently there is no requirement for equipment listed to UL 60950 to have nameplate ratings. Without a nameplate rating, as required for Class 2 and Class 3 power sources, it is difficult to know or find the rated output voltage and current of a power source.

The Committee Statement is correct for Class 2 and Class 3 power sources. That is, the output wiring is not permitted to be paralleled, unless listed for the application, and the text preceding Tables 11(A) and (B) in Chapter 9 requires the “power source shall be durably marked where plainly visible to indicate the class of supply and its electrical rating.”

However, the above paragraph applies to Class 2 and Class 3 power sources. It does not apply to power sources listed in compliance with UL 60950. It is important for installation, inspection and evaluation of the system for change to have the nameplate ratings marked on the equipment.

While listed equipment may contain listed or “Recognized” power sources, the text of the requirement addresses the outputs of the listed equipment.

Committee Action: Rejected but see related SR
Resolution: SR-614-NFPA 70-2015
Statement: This new section provides appropriate references to other Sections within Article 725 that apply to Power and Data Transmission equipment. Marking of the output connections was referred back to 725.121(C) where the marking requirement originates.
Public Comment No. 235-NFPA 70-2015 [ New Part after IX. ]

Review and accept PI 1303.
I respectfully request the CMP to review PI 1303 again and consider the substantiation I am providing during the Public Comments.

Statement of Problem and Substantiation for Public Comment

Currently, there are no provisions for secondary conductors for installations over 1000V similar to the tap rules in 240.21. Adding these requirements would allow secondary conductors over 1000V to be used as they are today. It clearly states in Article 240, I. General, that only part IX applies to over 1000V.

It is very common for secondary conductors to be installed without overcurrent protection at the transformer secondary on medium voltage installations such as 4160v and 13.8kV systems. The secondary conductors are typically cable, cable bus, or bus duct. The low voltage tap rules have erroneously been used for years for medium voltage installations. There isn't any issue with the words that I've proposed as far as safety goes to the best of my knowledge. This is being done all over the world and the NEC hasn't caught up with what is going on.

I think this addition would allow what is being done already to continue to be done and provide the inspection authority with something to inspect by other than just engineered drawings.

The rules as proposed should be adequate for medium voltage as well as low voltage as amps are amps and volts are volts.

### Committee Statement

- **Committee Action**: Rejected but see related SR
- **Resolution**: SR-4564-NFPA 70-2015
- **Statement**: The requirements proposed in the First Draft are outside the scope of Chapter 8 as well as the title and scope of Article 840. However, wording was added to direct the user to 725.144 for power delivery circuits that exceed 60 watts on communications cables.
Part VI. Premises Powering of Communications Equipment over Communications Wires and Cables, including Coaxial Cables

Informational Note: This Part addresses types of circuits intended to provide power over coaxial cables and premises powering circuits over communications wires and cables, to remote equipment, including systems such as Power over Ethernet (PoE). These premises-powering systems do not include circuits such as those that provide plain, coaxial cables. Plain old telephone services (POTS), traditional CATV services, and similar legacy communications services do not contain premises powering circuits.

Statement of Problem and Substantiation for Public Comment

The title needs to include the cable types being addressed, communications wire and cable, including coaxial cable. The informational note should not include intentions of an Article as this could be mis-leading or mis-interpreted. Powering may not be just to remote equipment, but may also be for source equipment. We also need to delete reference to “Power over Ethernet (PoE) or include all systems, which would be extensive and burdensome.

Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4564-NFPA 70-2015
Statement: The requirements proposed in the First Draft are outside the scope of Chapter 8 as well as the title and scope of Article 840. However, wording was added to direct the user to 725.144 for power delivery circuits that exceed 60 watts on communications cables.
Part VI. Premises Powering of Communications Equipment over Communications Cables

Informational Note: This Part addresses types of circuits intended to provide power over coaxial cables and communications wires and cables to remote equipment, including systems such as Power over Ethernet (PoE) and IP telephones (VOIP). These premises-powering systems do not include circuits such as those that provide plain old telephone services (POTS), traditional CATV services, and similar legacy communications services.

840.160 Powering Circuits.

Communications cables, in addition to carrying the communications circuit, shall also be permitted to carry circuits for powering communications equipment.

The communications cables and the powering circuits shall comply with 840.160(A), (B), and (C), as applicable.

(A) Power Limitations.

The power circuits shall comply with the requirements of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc.

Informational Note: The 100 VA (100 W) power source maximum nameplate rating in Chapter 9, Table 11(B) is the same as the maximum power rating for network-powered broadband communications systems in Table 830.15, the communications industry standard in ATIS-0600337.2010, Requirements for Maximum Voltage, Current, and Power Levels in Network-Powered Transport Systems, and UL 60950-1-2014, Information Technology Equipment - Safety - Part 21: Remote Power Feeding.

Informational Note No. 2: A cable used for simultaneously communicating with and powering of communications equipment could be connected to a power source capable of providing up to the Class 2 limit in Chapter 9, Table 11B, that is, 100 VA of power per pair.

(B) Ampacity.

The maximum current carried by each communications conductor shall conform to Table 840.160(A). Informational Note: The ampacity of the small wire gauges is the same as the maximum power rating for network-powered broadband communications systems in Table 830.15, the communications industry standard in ATIS-0600337.2010, Requirements for Maximum Voltage, Current, and Power Levels in Network-Powered Transport Systems, and UL 60950-1-2014, Information Technology Equipment - Safety - Part 21: Remote Power Feeding.

Informational Note No. 2: A cable used for simultaneously communicating with and powering of communications equipment could be connected to a power source capable of providing up to the Class 2 limit in Chapter 9, Table 11B, that is, 100 VA of power per pair.
Cables Supplying Premises Power and Communications. Installations of cables used to supply power to communications equipment and to communicate with communications equipment shall comply with 840.160(B)(1) or (B)(2).

1. Types CMP, CMR, CMG and CM Cables. In addition to communications, Types CMP, CMR, CMG and CM cables shall be permitted to supply power to communications equipment in accordance with power limitations of 840.160(A) and the ampacity limitations of 840.160(C).

   Informational Note: One example of the use of Type CMR cables is a network of remote powered IP telephones using 24 AWG, 60°C Type CMR, Category 5e LAN (local area network) cables.

2. Types CMP-LP(xxA), CMR-LP(xxA), CMG-LP(xxA) and CM-LP(xxA) Cables. Types CMP-LP(xxA), CMR-LP(xxA), CMG-LP(xxA) and CM-LP(xxA) shall be permitted to supply power to communications equipment at a current level per conductor up to the marked ampere limit (xx) and to communicate with communications equipment. The installation of Types CMP-LP(xxA), CMR-LP(xxA), CMG-LP(xxA) and CM-LP(xxA) shall be in accordance with the installation requirements for Types CMP, CMR, CMG and CM, respectively, in Article 800, Part V, Installation Methods Within Buildings. LP cables shall also be permitted to be used within the bundle size and ampacity limitations of 840.160(C).

   Informational Note: One example of a limited power cable is a cable listed and marked Type CMP-LP(0.5A), 23 AWG. Type CMP-LP(0.5A) can be used in any location where a Type CMP can be used and the cable would be suitable for carrying up to 0.5 A per conductor regardless of bundle size. If used in a 7 cable group, Table 840.160(C) indicates that the same cable could carry up to 1.2 amperes per conductor because it is 23 AWG.

3. Current Limitations and Ampacity. The maximum current carried by each conductor in Types CMP, CMR, CMG and CM cables shall conform to the ampacity limits of Table 840.160(CA) for ambient temperatures up to 30°C (86°F). For ambient temperatures above 30°C (86°F), the correction factors of 310.15(B)(2) shall be permitted to be used. The maximum current carried by connectors shall not exceed the recognized current carrying limit of the connector.

   Informational Note: No.1: The ampacity of wire gauges smaller than 18AWG, including 26 to 22 AWG typically used in communications cables are not included in the ampacity tables in Article 310.

4. Installations of New Cables.

   New cables installed for carrying both communications and power, where the maximum adjusted ampacity of conductors exceed the values in

   Informational Note No. 2: It is generally accepted that modular connectors such as RJ-45 are suitable for up to 1.3A, consequently the maximum permitted current in a conductor in a cable may be due to the current limits of the connector and not the ampacity of the cable conductors. Table 840.160(A).

5. Using Cables Without the “LP” Marking for Supplying Premises Power and Communications.

   New and existing cables without the “LP” marking shall be permitted to connect to communications equipment that supplies communications and power in accordance with the voltage and power limitations of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc, provided that the maximum current supplied by the power source is less than the adjusted ampacity of conductors in Table 840.160(A). For ambient temperatures other then 30°C (86°F) ampacity shall be permitted to be adjusted per Table 310.15(B)(2)(a).

   Communications Conductor Ampacity Based

   Table 840.160(C), Ampacities of Each Conductor (in Amperes) in a 4-Pair Communications Cable, Based on Copper Conductors at Ambient Temperature of 30°C (86°F) with all Conductors in All Cables Carrying Current. 60°C (140°F), 75°C (167°F) and 90°C (194°F) Rated Cables.

Public Comment No. 636-NFPA 70-2015 [Sections Part VI., 840.160]

**Sections Part VI., 840.160**

**Premises Powering of Communications Equipment over Communications Cables**

**Informational Note:** This Part addresses types of circuits intended to provide power over coaxial cables and communications wires and cables to remote equipment, including systems such as Power over Ethernet (PoE). These premises-powering systems do not include circuits such as those that provide plain old telephone services (POTS), traditional CATV services, and similar legacy communications services.

**840.160 – Powering Circuits.**

Communications cables, in addition to carrying the communications circuit, shall also be permitted to carry circuits for powering communications equipment. The communications cables and the powering circuits shall comply with 840.160(A), (B), and (C), as applicable.

**(A) – Power Limitations.**

The power circuits shall comply with the requirements of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc.

**Informational Note:** The 100 VA (100 W) power source maximum nameplate rating in Chapter 9, Table 11(B) is the same as the maximum power rating for network-powered broadband communications systems in Table 830.15, the communications industry standard in ATIS-0600337.2010, *Requirements for Maximum Voltage, Current, and Power Levels in Network-Powered Transport Systems*, and UL 60950-1, *Information Technology Equipment Safety Part 21: Remote Power Feeding*.

</table>

**Informational Note:** The conductor size of existing communications cable, including “category X” type cables, can be as small as 26 AWG.

**(B) – Ampacity.**

The maximum current carried by each communications conductor shall conform to Table 840.160(A).

**Informational Note:** The ampacity of the small wire gauges used in communications cables are not included in the ampacity tables in Article 310.

**(C) – Installations of New Cables.**

New cables installed for carrying both communications and power, where the maximum adjusted ampacity of conductors exceed the values in Table 840.160(A), shall be Type CMP-LP, CMR-LP, or CM-LP, as applicable.

**(D) – Using Cables Without the “LP” Marking for Supplying Premises Power and Communications.**

New and existing cables without the “LP” marking shall be permitted to connect to communications equipment that supplies communications and power in accordance with the voltage and power limitations of Table 11(B) in Chapter 9 for voltage sources up to 60 V dc, provided that the maximum current supplied by the power source is less than the adjusted ampacity of conductors in Table 840.160(A). For ambient temperatures other than 30°C (86°F), ampacity shall be permitted to be adjusted per Table 310.15(B)(2)(a).

**Additional Proposed Changes**

- **File Name**: Table_840.160_A_.docx
- **Description Approved**

**Statement of Problem and Substantiation for Public Comment**

The committee statement and original public input indicate that the problem being addressed is “each successive revision of the PoE standards delivers more power to the powered devices raising concern about overheating of the cables”. No incident data was provided nor any research data demonstrating this concern. Accordingly, it appears that an existing safety issue has not been shown. On related public comments (1837, 2366), CMP-3 correctly indicated that the public input does not meet the requirements of 4.3.4.1(d) of the Regulations Governing the Development of NFPA Standards in as much that technical substantiation was not provided in regard to the new cables for Class-2 or 3 circuits, new suffix “LP”. It appears that a standard for Listing “LP” cables has not yet been published and that research is ongoing.

Because no evidence of a hazard has been provided, and until sufficient data is provided and a consensus based product standard is available for suffix “LP” cables, it is premature to add these requirements to the Code.
Committee Statement

Committee Action: Rejected but see related SR
Resolution: SR-4564-NFPA 70-2015
Statement: The requirements proposed in the First Draft are outside the scope of Chapter 8 as well as the title and scope of Article 840. However, wording was added to direct the user to 725.144 for power delivery circuits that exceed 60 watts on communications cables.
Statement of Problem and Substantiation for Public Comment

Part VIII was supposed to be deleted according to the resolution logs. This section was erroneously retained. All energy storage language from Article 690 has been utilized in the new Article 706 - Energy Storage Systems. This deletion also includes all of 690.71, 690.72, and 690.74.

Submittal Date: Mon Sep 14 15:56:47 EDT 2015

Committee Statement

Committee Action: Rejected
Resolution: The panel decides to keep Part VIII for now and replace the content with a reference to Article 706 so that those who look to this section are properly directed to the appropriate Article.
Permit Conduit Fill Greater than 40% for Existing Runs

11) When installing 3 single conductor medium voltage shielded cables rated 5 kV or higher, with or without a ground conductor, in existing underground duct, the 40% fill limit may be exceeded provided there is 1/2" minimum clearance between the cables and duct.

Statement of Problem and Substantiation for Public Comment

The panels statement on my original proposal is confusing since this is cable in duct and lays on the bottom of the duct. Not sure how it would be confused with cable suspended in a raceway.

A fact finding Fact Finding Report is not needed since this has been common practice in NEC and non-NEC installations for as long as medium voltage cables have been around. Ampacity calculations were submitted with the proposal that demonstrated the cable will not run any hotter. Sound current engineering practices and current guidelines on cable jamming were also submitted. The proposal was well documented and based on sound engineering practice.

Limiting percent fill on existing runs for medium voltage cable only adds unnecessary excess cost and hardship to the end user.

Notes:
1. These resistance values are valid only for the parameters as given. Using conductors having coated strands, different stranding type, and,
even with a different temperature, changes the resistance.
2. Equation for temperature change: $R_2 = R_1 [1 + a (T_2 - T_1)]$, where $a_{Cu} = 0.00323$, $a_{Al} = 0.00330$ at 75°C.
3. Conductors with compact and compressed stranding have about 9 percent and 3 percent, respectively, smaller bare conductor diameters than those shown. See Table 5A for actual cable dimensions.
4. The IACS conductivities used: bare copper = 100%, aluminum = 61%.
5. Class B stranding is listed as well as solid for some sizes. Its overall diameter and area are those of its cross-sectional circle.

Informational Note: The construction information is in accordance with NEMA WC 7 2009-2013, or ANSI/JUL.

Statement of Problem and Substantiation for Public Comment

Referenced current NEMA edition, and updated NBS Handbooks to NIST Special Publication in Table 8 Note 5, informational note.
